Cardano.BM - benchmarking and logging

Alexander Diemand Andreas Triantafyllos

November 2018

Abstract

This is a framework that combines logging, benchmarking and monitoring. Complex evaluations of STM or monadic actions can be observed from outside while reading operating system counters before and after, and calculating their differences, thus relating resource usage to such actions. Through interactive configuration, the runtime behaviour of logging or the measurement of resource usage can be altered. Further reduction in logging can be achieved by redirecting log messages to an aggregation function which will output the running statistics with less frequency than the original message.

Contents

Chapter 1

Logging, benchmarking and monitoring

1.1 Overview

In figure 1.1 we display the relationships among modules in *Cardano.BM*. The arrows indicate import of a module. The arrows with a triangle at one end would signify "inheritance" in object-oriented programming, but we use it to show that one module replaces the other in the namespace, thus refines its interface.

1.2 Introduction

1.2.1 Logging with Trace

1.2.2 Setup procedure

Hierarchy of Traces

1.2.3 Measuring *Observable*s

1.2.4 Information reduction in Aggregation

1.2.5 Output selection

1.2.6 Monitoring

1.3 Examples

1.3.1 Observing evaluation of a STM action

1.3.2 Observing evaluation of a monad action

1.3.3 Simple example showing plain logging

```
{-# LANGUAGE OverloadedStrings #-}
module Main
  (main)
  where
import Control.Concurrent (threadDelay)
import Cardano.BM.Configuration.Static (defaultConfigStdout)
```

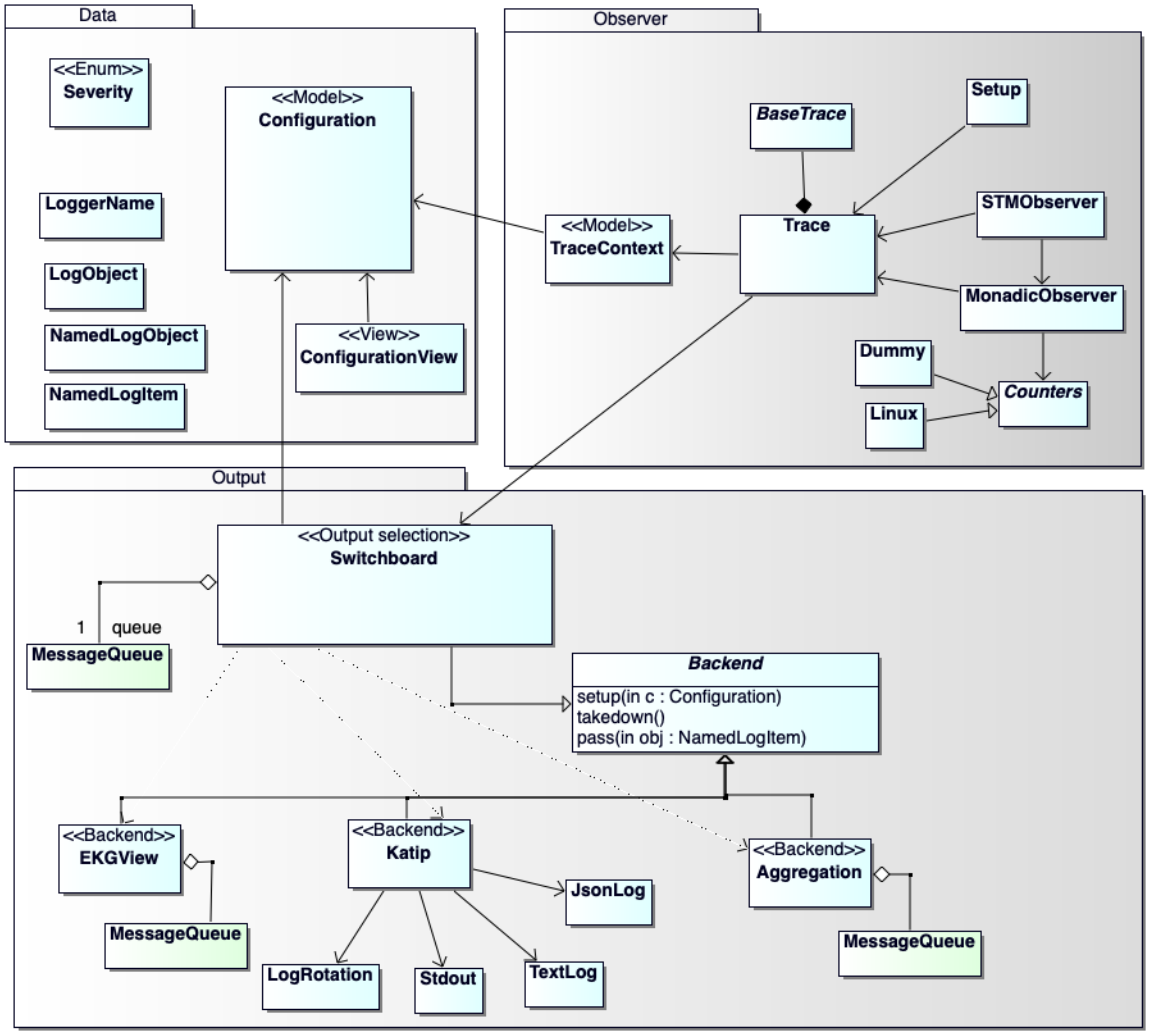

Figure 1.1: Overview of module relationships

```
import Cardano.BM.Setup (setupTrace)
import Cardano.BM.Trace (logDebug, logError, logInfo, logNotice,
                         logWarning)

main :: IO ()
main = do
  c ← defaultConfigStdout
  tr ← setupTrace (Right c) "simple"
  logDebug tr "this is a debug message"
  logInfo  tr "this is an information."
  logNotice tr "this is a notice!"
  logWarning tr "this is a warning!"
  logError  tr "this is an error!"
  threadDelay 80000
```

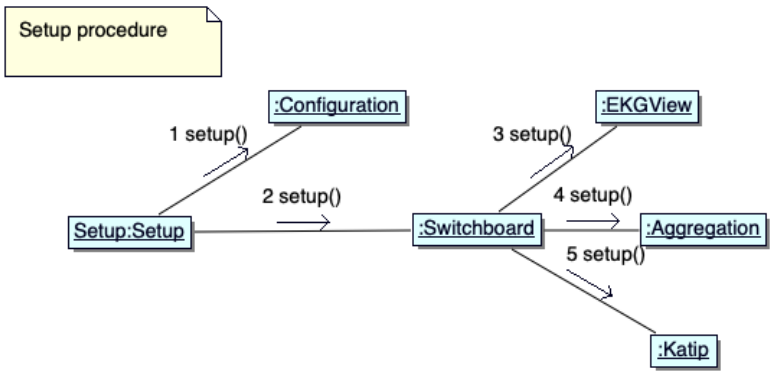

Figure 1.2: Setup procedure

return ()

1.3.4 Complex example showing logging, aggregation of log items, and observing *IO* actions

Module header and import directives

```
{-# LANGUAGE OverloadedStrings #-}
module Main
  (main)
  where
import Control.Concurrent (threadDelay)
import qualified Control.Concurrent.Async as Async
import Control.Monad (forM, forM_)
import GHC.Conc.Sync (STM, TVar, atomically, newTVar, readTVar, writeTVar)
import Data.Text (pack)
import System.Random
import qualified Cardano.BM.Configuration.Model as CM
import Cardano.BM.Data.Aggregated (Measurable (..))
import Cardano.BM.Data.AggregatedKind
import Cardano.BM.Data.BackendKind
import Cardano.BM.Data.LogItem
import Cardano.BM.Data.Observable
import Cardano.BM.Data.Output
import Cardano.BM.Data.Severity
import Cardano.BM.Data.SubTrace
import Cardano.BM.Observer.Monadic (bracketObserveIO)
import qualified Cardano.BM.Observer.STM as STM
import Cardano.BM.Setup
import Cardano.BM.Trace
```

Define configuration

The output can be viewed in EKG on `http://localhost:12789`.

```
config :: IO CM.Configuration
config = do

```

Thread that outputs a random number to a Trace

```
randomThr :: Trace IO → IO (Async.Async ())
randomThr trace = do
  logInfo trace "starting random generator"
  trace' ← subTrace "random" trace
  proc ← Async.async (loop trace')
  return proc
  where
    loop tr = do
      threadDelay 500000-- 0.5 second
      num ← randomRIO (42 - 42, 42 + 42) :: IO Double
      lo ← LogObject <$> mkLOMeta <*> pure (LogValue "rr" (PureD num))
      traceNamedObject tr lo
      loop tr
```

Thread that observes an *IO* action

```
observeIO :: Trace IO → IO (Async.Async ())
observeIO trace = do
  logInfo trace "starting observer"
  proc ← Async.async (loop trace)
  return proc
  where
    loop tr = do
      threadDelay 5000000-- 5 seconds
      _ ← bracketObserveIO tr "observeIO" $ do
        num ← randomRIO (100000, 200000) :: IO Int
        ls ← return $ reverse $ init $ reverse $ 42 : [1 .. num]
        pure $ const ls ()
      loop tr
```

Thread that observes an *IO* action which downloads a txt in order to observe the I/O statistics

disabled for now! on Mac OSX this function was blocking all IO.

```
observeDownload :: Trace IO → IO ()
observeDownload trace = loop trace
  where
    loop tr = do
      threadDelay 10000000-- 10 seconds
      tr' ← appendName "observeDownload" tr
      bracketObserveIO tr' "" $ do
        license ← openURI "http://www.gnu.org/licenses/gpl.txt"
        case license of
          Right bs → logNotice tr' $ pack $ take 100 $ BS8.unpack bs
          Left _ → return ()
        threadDelay 500000-- .5 second
        pure ()
      loop tr
```

Threads that observe *STM* actions on the same TVar

```
observeSTM :: Trace IO → IO [Async.Async ()]
observeSTM trace = do
  logInfo trace "starting STM observer"
  tvar ← atomically $ newTVar ([1 .. 1000] :: [Int])
  -- spawn 10 threads
  proc ← forM [(1 :: Int) .. 10] $ λx → Async.async (loop trace tvar (pack $ show x))
  return proc
  where
    loop tr tvarlist name = do
```

```
        threadDelay 10000000-- 10 seconds
        STM.bracketObserveIO tr ("observeSTM." <> name) (stmAction tvarlist)
        loop tr tvarlist name
stmAction :: TVar [Int] → STM ()
stmAction tvarlist = do
  list ← readTVar tvarlist
  writeTVar tvarlist $ reverse $ init $ reverse $ list
  pure ()
```

Thread that periodically outputs a message

```
msgThr :: Trace IO → IO (Async.Async ())
msgThr trace = do
  logInfo trace "start messaging .."
  trace' ← subTrace "message" trace
  Async.async (loop trace')
  where
    loop tr = do
      threadDelay 3000000-- 3 seconds
      logNotice tr "N O T I F I C A T I O N ! ! !"
      logDebug tr "a detailed debug message."
      logError tr "Boooommm .."
      loop tr
```

Main entry point

```
main :: IO ()
main = do
  -- create configuration
  c ← config
  -- create initial top-level Trace
  tr ← setupTrace (Right c) "complex"
  logNotice tr "starting program; hit CTRL-C to terminate"
  logInfo tr "watch its progress on http://localhost:12789"
   {-start thread sending unbounded sequence of random numbers to a trace which aggregates them into a
  procRandom ← randomThr tr
  -- start thread endlessly reversing lists of random length
  procObsvIO ← observeIO tr
  -- start threads endlessly observing STM actions operating on the same TVar
  procObsvSTMs ← observeSTM tr
  -- start a thread to output a text messages every n seconds
  procMsg ← msgThr tr
  -- wait for message thread to finish, ignoring any exception
```

```
    _ ← Async.waitCatch procMsg
    -- wait for observer thread to finish, ignoring any exception
    _ ← forM procObsvSTMs Async.waitCatch
    -- wait for observer thread to finish, ignoring any exception
    _ ← Async.waitCatch procObsvIO
    -- wait for random thread to finish, ignoring any exception
    _ ← Async.waitCatch procRandom
    return ()
```

1.4 Code listings

1.4.1 Cardano.BM.Observer.STM

```
stmWithLog :: STM.STM (t, [LogObject]) → STM.STM (t, [LogObject])
stmWithLog action = action
```

Observe *STM* action in a named context

With given name, create a SubTrace according to Configuration and run the passed *STM* action on it.

```
bracketObserveIO :: Trace IO → Text → STM.STM t → IO t
bracketObserveIO logTrace0 name action = do
    logTrace ← subTrace name logTrace0
    let subtrace = typeofTrace logTrace
    bracketObserveIO' subtrace logTrace action
  where
    bracketObserveIO' :: SubTrace → Trace IO → STM.STM t → IO t
    bracketObserveIO' NoTrace _ act =
      STM.atomically act
    bracketObserveIO' subtrace logTrace act = do
      mCountersid ← observeOpen subtrace logTrace
      -- run action; if an exception is caught will be logged and rethrown.
      t ← (STM.atomically act) `catch` (λ(e :: SomeException) → (logError logTrace (pack (show e)) ≫ throwM e)
      case mCountersid of
        Left openException →
          -- since observeOpen faced an exception there is no reason to call observeClose
          -- however the result of the action is returned
          logNotice logTrace ("ObserveOpen: " <> pack (show openException))
        Right countersid → do
          res ← observeClose subtrace logTrace countersid [ ]
          case res of
            Left ex → logNotice logTrace ("ObserveClose: " <> pack (show ex))
            _ → pure ()
      pure t
```

Observe *STM* action in a named context and output captured log items

The *STM* action might output messages, which after "success" will be forwarded to the logging trace. Otherwise, this function behaves the same as Observe *STM* action in a named context.

```
bracketObserveLogIO :: Trace IO → Text → STM.STM (t, [LogObject]) → IO t
bracketObserveLogIO logTrace0 name action = do
    logTrace ← subTrace name logTrace0
    let subtrace = typeofTrace logTrace
    bracketObserveLogIO' subtrace logTrace action
  where
    bracketObserveLogIO' :: SubTrace → Trace IO → STM.STM (t, [LogObject]) → IO t
    bracketObserveLogIO' NoTrace _ act = do
      (t, _) ← STM.atomically $ stmWithLog act
      pure t
    bracketObserveLogIO' subtrace logTrace act = do
      mCountersid ← observeOpen subtrace logTrace
      -- run action, return result and log items; if an exception is
      -- caught will be logged and rethrown.
      (t, as) ← (STM.atomically $ stmWithLog act) `catch`
          (λ(e :: SomeException) → (logError logTrace (pack (show e)) ≫ throwM e))
      case mCountersid of
        Left openException →
          -- since observeOpen faced an exception there is no reason to call observeClose
          -- however the result of the action is returned
          logNotice logTrace ("ObserveOpen: " <> pack (show openException))
        Right countersid → do
          res ← observeClose subtrace logTrace countersid as
          case res of
            Left ex → logNotice logTrace ("ObserveClose: " <> pack (show ex))
            _ → pure ()
      pure t
```

1.4.2 Cardano.BM.Observer.Monadic

Monadic.bracketObserverIO

Observes an *IO* action and adds a name to the logger name of the passed in Trace. An empty *Text* leaves the logger name untouched.

Microbenchmarking steps:

1. Create a *trace* which will have been configured to observe things besides logging.

```
import qualified Cardano.BM.Configuration.Model as CM
 ○ ○ ○
c ← config
trace@(ctx, _) ← setupTrace (Right c) "demo-playground"
```

```
  where
    config :: IO CM.Configuration
    config = do
      c ← CM.empty
      CM.setMinSeverity c Debug
      CM.setSetupBackends c [KatipBK, AggregationBK]
      CM.setDefaultBackends c [KatipBK, AggregationBK]
      CM.setSetupScribes c [ScribeDefinition {
        scName = "stdout"
        ,scKind = StdoutSK
        ,scRotation = Nothing
        }
        ]
      CM.setDefaultScribes c ["StdoutSK::stdout"]
      return c
```

2. *c* is the Configuration of *trace*. In order to enable the collection and processing of measurements (min, max, mean, std-dev) *AggregationBK* is needed.

```
CM.setDefaultBackends c [KatipBK, AggregationBK]
```

in a configuration file (YAML) means

```
defaultBackends:
  - KatipBK
  - AggregationBK
```

3. Set the measurements that you want to take by changing the configuration of the *trace* using *setSubTrace*, in order to declare the namespace where we want to enable the particular measurements and the list with the kind of measurements.

```
CM.setSubTrace
    (configuration ctx)
    "demo-playground.submit-tx"
    (Just $ ObservableTrace observablesSet)
  where
    observablesSet = [MonotonicClock, MemoryStats]
```

4. Find an action to measure. e.g.:

```
runProtocolWithPipe x hdl proto `catch` (λProtocolStopped → return ())
```

and use bracketObserveIO. e.g.:

```
bracketObserveIO trace "submit-tx" $
  runProtocolWithPipe x hdl proto `catch` (λProtocolStopped → return ())
```

```
bracketObserveIO :: Trace IO → Text → IO t → IO t
bracketObserveIO logTrace0 name action = do
```

```
    logTrace ← subTrace name logTrace0
    bracketObserveIO' (typeofTrace logTrace) logTrace action
  where
    bracketObserveIO' :: SubTrace → Trace IO → IO t → IO t
    bracketObserveIO' NoTrace _ act = act
    bracketObserveIO' subtrace logTrace act = do
      mCountersid ← observeOpen subtrace logTrace
      -- run action; if an exception is caught will be logged and rethrown.
      t ← act `catch` (λ(e :: SomeException) → (logError logTrace (pack (show e)) ≫ throwM e))
      case mCountersid of
        Left openException →
          -- since observeOpen faced an exception there is no reason to call observeClose
          -- however the result of the action is returned
          logNotice logTrace ("ObserveOpen: " <> pack (show openException))
        Right countersid → do
          res ← observeClose subtrace logTrace countersid [ ]
          case res of
            Left ex → logNotice logTrace ("ObserveClose: " <> pack (show ex))
            _ → pure ()
      pure t
```

Monadic.bracketObserverM

Observes a *MonadIO m* ⇒ *m* action and adds a name to the logger name of the passed in Trace. An empty *Text* leaves the logger name untouched.

```
bracketObserveM :: (MonadCatch m, MonadIO m) ⇒ Trace IO → Text → m t → m t
bracketObserveM logTrace0 name action = do
    logTrace ← liftIO $ subTrace name logTrace0
    bracketObserveM' (typeofTrace logTrace) logTrace action
  where
    bracketObserveM' :: (MonadCatch m, MonadIO m) ⇒ SubTrace → Trace IO → m t → m t
    bracketObserveM' NoTrace _ act = act
    bracketObserveM' subtrace logTrace act = do
      mCountersid ← liftIO $ observeOpen subtrace logTrace
      -- run action; if an exception is caught will be logged and rethrown.
      t ← act `catch`
        (λ(e :: SomeException) → (liftIO (logError logTrace (pack (show e)) ≫ throwM e)))
      case mCountersid of
        Left openException →
          -- since observeOpen faced an exception there is no reason to call observeClose
          -- however the result of the action is returned
          liftIO $ logNotice logTrace ("ObserveOpen: " <> pack (show openException))
        Right countersid → do
          res ← liftIO $ observeClose subtrace logTrace countersid [ ]
          case res of
            Left ex → liftIO (logNotice logTrace ("ObserveClose: " <> pack (show ex)))
```

```
                _ → pure ()
        pure t
```

observerOpen

```
observeOpen :: SubTrace → Trace IO → IO (Either SomeException CounterState)
observeOpen subtrace logTrace = (do
  identifier ← newUnique
  -- take measurement
  counters ← readCounters subtrace
  let state = CounterState identifier counters
  if counters ≡ [ ]
  then return ()
  else do
    -- send opening message to Trace
    traceNamedObject logTrace =≪
      LogObject <$> mkLOMeta <*> pure (ObserveOpen state)
  return (Right state)) `catch` (return ∘ Left)
```

observeClose

```
observeClose :: SubTrace → Trace IO → CounterState → [LogObject] → IO (Either SomeException ())
observeClose subtrace logTrace initState logObjects = (do
  let identifier = csIdentifier initState
      initialCounters = csCounters initState
  -- take measurement
  counters ← readCounters subtrace
  if counters ≡ [ ]
  then return ()
  else do
    mle ← mkLOMeta
    -- send closing message to Trace
    traceNamedObject logTrace $
      LogObject mle (ObserveClose (CounterState identifier counters))
    -- send diff message to Trace
    traceNamedObject logTrace $
      LogObject mle (ObserveDiff (CounterState identifier (diffCounters initialCounters counters)))
  -- trace the messages gathered from inside the action
  forM_ logObjects $ traceNamedObject logTrace
  return (Right ())) `catch` (return ∘ Left)
```

1.4.3 BaseTrace

Contravariant

A covariant is a functor: F A → F B
A contravariant is a functor: F B → F A

Op a b implements the inverse to 'arrow' *"getOp :: b → a"*, which when applied to a BaseTrace of type *"Op (m ()) s"*, yields *"s → m ()"*. In our case, *Op* accepts an action in a monad *m* with input type LogNamed LogObject (see 'Trace').

```
newtype BaseTrace m s = BaseTrace {runTrace :: Op (m ()) s}
```

contramap

A covariant functor defines the function *"fmap :: (a → b) → f a → f b"*. In case of a contravariant functor, it is the dual function *"contramap :: (a → b) → f b → f a"* which is defined.

In the following instance, *runTrace* extracts type *"Op (m ()) s"* to which contramap applies *f*, thus *"f s → m ()"*. The constructor BaseTrace restores *"Op (m ()) (f s)"*.

```
instance Contravariant (BaseTrace m) where
  contramap f = BaseTrace ∘ contramap f ∘ runTrace
```

traceWith

Accepts a Trace and some payload *s*. First it gets the contravariant from the Trace as type *"Op (m ()) s"* and, after *"getOp::b → a"* which translates to *"s → m ()"*, calls the action on the LogNamed LogObject.

```
traceWith :: BaseTrace m s → s → m ()
traceWith = getOp ∘ runTrace
```

natTrace

Natural transformation from monad *m* to monad *n*.

```
natTrace :: (forall x ∘ m x → n x) → BaseTrace m s → BaseTrace n s
natTrace nat (BaseTrace (Op tr)) = BaseTrace $ Op $ nat ∘ tr
```

noTrace

A Trace that discards all inputs.

```
noTrace :: Applicative m ⇒ BaseTrace m a
noTrace = BaseTrace $ Op $ const (pure ())
```

1.4.4 Cardano.BM.Trace

Utilities

Natural transformation from monad *m* to monad *n*.

```
natTrace :: (forall x ∘ m x → n x) → Trace m → Trace n
natTrace nat (ctx, trace) = (ctx, BaseTrace.natTrace nat trace)
```

Access type of Trace.

```
typeofTrace :: Trace m → SubTrace
typeofTrace (ctx, _) = tracetype ctx
```

Update type of Trace.

```
updateTracetype :: SubTrace → Trace m → Trace m
updateTracetype subtr (ctx, tr) = (ctx {tracetype = subtr}, tr)
```

Enter new named context

The context name is created and checked that its size is below a limit (currently 80 chars). The minimum severity that a log message must be labelled with is looked up in the configuration and recalculated.

```
appendName :: MonadIO m ⇒ LoggerName → Trace m → m (Trace m)
appendName name (ctx, trace) = do
  let prevLoggerName = loggerName ctx
      prevMinSeverity = minSeverity ctx
      newLoggerName   = appendWithDot prevLoggerName name
  globMinSeverity ← liftIO $ Config.minSeverity (configuration ctx)
  namedSeverity ← liftIO $ Config.inspectSeverity (configuration ctx) newLoggerName
  case namedSeverity of
    Nothing → return (ctx {loggerName = newLoggerName}, trace)
    Just sev → return (ctx {loggerName = newLoggerName
      , minSeverity = max (max sev prevMinSeverity) globMinSeverity}
      , trace)
appendWithDot :: LoggerName → LoggerName → LoggerName
appendWithDot "" newName = T.take 80 newName
appendWithDot xs "" = xs
appendWithDot xs newName = T.take 80 $ xs <> " . " <> newName
```

Contramap a trace and produce the naming context

```
named :: BaseTrace.BaseTrace m (LogNamed i) → LoggerName → BaseTrace.BaseTrace m i
named trace name = contramap (LogNamed name) trace
```

Trace a LogObject through

```
traceNamedObject
  :: MonadIO m
  ⇒ Trace m
  → LogObject
  → m ()
traceNamedObject trace@(ctx, logTrace) lo@(LogObject _ lc) = do
```

```
    let lname = loggerName ctx
    doOutput ← case (typeofTrace trace) of
      FilterTrace filters →
        case lc of
          LogValue loname _ →
            return $ evalFilters filters (lname <> " . " <> loname)
          _ →
            return $ evalFilters filters lname
      TeeTrace secName → do
        -- create a newly named copy of the LogObject
        BaseTrace.traceWith (named logTrace (lname <> " . " <> secName)) lo
        return True
      _ → return True
    if doOutput
    then BaseTrace.traceWith (named logTrace lname) lo
    else return ()
```

Evaluation of FilterTrace

A filter consists of a *DropName* and a list of *UnhideNames*. If the context name matches the *DropName* filter, then at least one of the *UnhideNames* must match the name to have the evaluation of the filters return *True*.

```
evalFilters :: [(DropName, UnhideNames)] → LoggerName → Bool
evalFilters fs nm =
    all (λ(no, yes) → if (dropFilter nm no) then (unhideFilter nm yes) else True) fs
  where
    dropFilter :: LoggerName → DropName → Bool
    dropFilter name (Drop sel) =  {-not -}  (matchName name sel)
    unhideFilter :: LoggerName → UnhideNames → Bool
    unhideFilter _ (Unhide [ ]) = False
    unhideFilter name (Unhide us) = any (λsel → matchName name sel) us
    matchName :: LoggerName → NameSelector → Bool
    matchName name (Exact name') = name ≡ name'
    matchName name (StartsWith prefix) = T.isPrefixOf prefix name
    matchName name (EndsWith postfix) = T.isSuffixOf postfix name
    matchName name (Contains name') = T.isInfixOf name' name
```

Concrete Trace on stdout

This function returns a trace with an action of type "(LogNamed LogObject) → *IO* ()" which will output a text message as text and all others as JSON encoded representation to the console.

TODO remove *locallock*

```
locallock :: MVar ()
locallock = unsafePerformIO $ newMVar ()
```

```
stdoutTrace :: TraceNamed IO
stdoutTrace = BaseTrace.BaseTrace $ Op $ λ(LogNamed logname (LogObject _ lc)) →
    withMVar locallock $ \_ →
      case lc of
        (LogMessage logItem) →
          output logname $ liPayload logItem
        obj →
          output logname $ toStrict (encodeToLazyText obj)
  where
    output nm msg = TIO.putStrLn $ nm <> "  ::  " <> msg
```

Concrete Trace into a *TVar*

```
traceInTVar :: STM.TVar [a] → BaseTrace.BaseTrace STM.STM a
traceInTVar tvar = BaseTrace.BaseTrace $ Op $ λa → STM.modifyTVar tvar ((:) a)

traceInTVarIO :: STM.TVar [LogObject] → TraceNamed IO
traceInTVarIO tvar = BaseTrace.BaseTrace $ Op $ λln →
  STM.atomically $ STM.modifyTVar tvar ((:) (lnItem ln))

traceNamedInTVarIO :: STM.TVar [LogNamed LogObject] → TraceNamed IO
traceNamedInTVarIO tvar = BaseTrace.BaseTrace $ Op $ λln →
  STM.atomically $ STM.modifyTVar tvar ((:) ln)
```

Check a log item's severity against the Trace's minimum severity

do we need three different minSeverity defined?

We do a lookup of the global minSeverity in the configuration. And, a lookup of the minSeverity for the current named context. These values might have changed in the meanwhile.
A third filter is the minSeverity defined in the current context.

```
traceConditionally
  :: MonadIO m
  ⇒ Trace m
  → LogObject
  → m ()
traceConditionally logTrace@(ctx, _) msg@(LogObject _ (LogMessage item)) = do
  globminsev ← liftIO $ Config.minSeverity (configuration ctx)
  globnamesev ← liftIO $ Config.inspectSeverity (configuration ctx) (loggerName ctx)
  let minsev = max (minSeverity ctx) $ max globminsev (fromMaybe Debug globnamesev)
      flag = (liSeverity item) ⩾ minsev
  when flag $ traceNamedObject logTrace msg
traceConditionally logTrace logObject =
  traceNamedObject logTrace logObject
```

Enter message into a trace

The function traceNamedItem creates a LogObject and threads this through the action defined in the Trace.

```
traceNamedItem
  :: MonadIO m
  ⇒ Trace m
  → LogSelection
  → Severity
  → T.Text
  → m ()
traceNamedItem trace p s m =
  traceConditionally trace =≪
    LogObject <$> liftIO mkLOMeta
      <*> pure (LogMessage LogItem {liSelection = p
        , liSeverity = s
        , liPayload  = m
        })
```

Logging functions

```
logDebug, logInfo, logNotice, logWarning, logError, logCritical, logAlert, logEmergency
  :: MonadIO m ⇒ Trace m → T.Text → m ()
logDebug     logTrace = traceNamedItem logTrace Both Debug
logInfo      logTrace = traceNamedItem logTrace Both Info
logNotice    logTrace = traceNamedItem logTrace Both Notice
logWarning logTrace = traceNamedItem logTrace Both Warning
logError     logTrace = traceNamedItem logTrace Both Error
logCritical  logTrace = traceNamedItem logTrace Both Critical
logAlert     logTrace = traceNamedItem logTrace Both Alert
logEmergency logTrace = traceNamedItem logTrace Both Emergency

logDebugS, logInfoS, logNoticeS, logWarningS, logErrorS, logCriticalS, logAlertS, logEmergencyS
  :: MonadIO m ⇒ Trace m → T.Text → m ()
logDebugS    logTrace = traceNamedItem logTrace Private Debug
logInfoS     logTrace = traceNamedItem logTrace Private Info
logNoticeS   logTrace = traceNamedItem logTrace Private Notice
logWarningS logTrace = traceNamedItem logTrace Private Warning
logErrorS    logTrace = traceNamedItem logTrace Private Error
logCriticalS logTrace = traceNamedItem logTrace Private Critical
logAlertS    logTrace = traceNamedItem logTrace Private Alert
logEmergencyS logTrace = traceNamedItem logTrace Private Emergency

logDebugP, logInfoP, logNoticeP, logWarningP, logErrorP, logCriticalP, logAlertP, logEmergencyP
  :: MonadIO m ⇒ Trace m → T.Text → m ()
logDebugP    logTrace = traceNamedItem logTrace Public Debug
logInfoP     logTrace = traceNamedItem logTrace Public Info
logNoticeP   logTrace = traceNamedItem logTrace Public Notice
```

```
logWarningP logTrace = traceNamedItem logTrace Public Warning
logErrorP    logTrace = traceNamedItem logTrace Public Error
logCriticalP logTrace = traceNamedItem logTrace Public Critical
logAlertP    logTrace = traceNamedItem logTrace Public Alert
logEmergencyP logTrace = traceNamedItem logTrace Public Emergency
logDebugUnsafeP, logInfoUnsafeP, logNoticeUnsafeP, logWarningUnsafeP, logErrorUnsafeP,
  logCriticalUnsafeP, logAlertUnsafeP, logEmergencyUnsafeP
  :: MonadIO m => Trace m -> T.Text -> m ()
logDebugUnsafeP    logTrace = traceNamedItem logTrace PublicUnsafe Debug
logInfoUnsafeP     logTrace = traceNamedItem logTrace PublicUnsafe Info
logNoticeUnsafeP   logTrace = traceNamedItem logTrace PublicUnsafe Notice
logWarningUnsafeP logTrace = traceNamedItem logTrace PublicUnsafe Warning
logErrorUnsafeP    logTrace = traceNamedItem logTrace PublicUnsafe Error
logCriticalUnsafeP logTrace = traceNamedItem logTrace PublicUnsafe Critical
logAlertUnsafeP    logTrace = traceNamedItem logTrace PublicUnsafe Alert
logEmergencyUnsafeP logTrace = traceNamedItem logTrace PublicUnsafe Emergency
```

subTrace

Transforms the input Trace according to the Configuration using the logger name of the current Trace appended with the new name. If the empty *Text* is passed, then the logger name remains untouched.

```
subTrace :: MonadIO m => T.Text -> Trace m -> m (Trace m)
subTrace name tr@(ctx, _) = do
  let newName = appendWithDot (loggerName ctx) name
  subtrace0 <- liftIO $ Config.findSubTrace (configuration ctx) newName
  let subtrace = case subtrace0 of Nothing -> Neutral; Just str -> str
  case subtrace of
    Neutral       -> do
                     tr' <- appendName name tr
                     return $ updateTracetype subtrace tr'
    UntimedTrace -> do
                     tr' <- appendName name tr
                     return $ updateTracetype subtrace tr'
    TeeTrace _    -> do
                     tr' <- appendName name tr
                     return $ updateTracetype subtrace tr'
    FilterTrace _ -> do
                     tr' <- appendName name tr
                     return $ updateTracetype subtrace tr'
    NoTrace       -> return $ updateTracetype subtrace (ctx, BaseTrace.BaseTrace $ Op $ \_ -> pure ())
    DropOpening -> return $ updateTracetype subtrace (ctx, BaseTrace.BaseTrace $ Op $
                     \(LogNamed _ lo@(LogObject _ lc)) -> do
                       case lc of
                         ObserveOpen _ -> return ()
                         _ -> traceNamedObject tr lo)
```

```
    ObservableTrace _ → do
                        tr' ← appendName name tr
                        return $ updateTracetype subtrace tr'
```

1.4.5 Cardano.BM.Setup

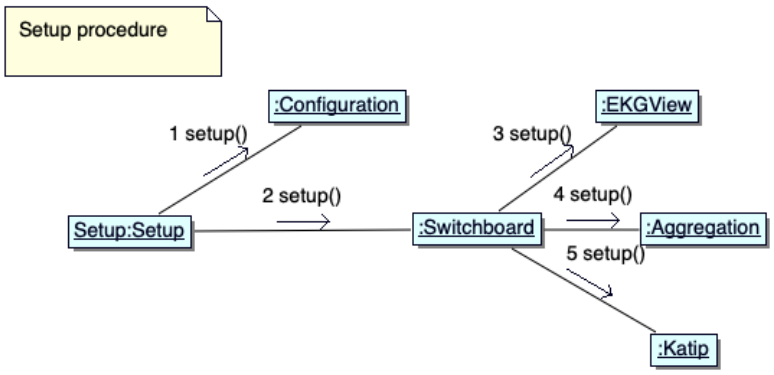

Figure 1.3: Setup procedure

setupTrace

Setup a new Trace (Trace) with either a given Configuration (Configuration.Model) or a *FilePath* to a configuration file. After all tracing operations have ended; shutdownTrace must be called.

```
setupTrace :: MonadIO m ⇒ Either FilePath Config.Configuration → Text → m (Trace m)
setupTrace (Left cfgFile) name = do
  c ← liftIO $ Config.setup cfgFile
  setupTrace_ c name
setupTrace (Right c) name = setupTrace_ c name

setupTrace_ :: MonadIO m ⇒ Config.Configuration → Text → m (Trace m)
setupTrace_ c name = do
  sb ← liftIO $ Switchboard.realize c
  sev ← liftIO $ Config.minSeverity c
  ctx ← liftIO $ newContext "" c sev sb

  subTrace name $ natTrace liftIO (ctx, Switchboard.mainTrace sb)
```

shutdownTrace

Shut down a Trace and all the Traces related to it.

```
shutdownTrace :: MonadIO m ⇒ Trace m → m ()
shutdownTrace (ctx, _) = liftIO $ shutdown ctx
```

withTrace

```
withTrace :: (MonadIO m, MonadMask m) ⇒ Config.Configuration → Text → (Trace m → m t) → m t
withTrace cfg name action =
  bracket (setupTrace (Right cfg) name) shutdownTrace action
```

newContext

```
newContext :: LoggerName
  → Config.Configuration
  → Severity
  → Switchboard.Switchboard
  → IO TraceContext
newContext name cfg sev sb = do
  return $ TraceContext {
    loggerName = name
    , configuration = cfg
    , minSeverity = sev
    , tracetype = Neutral
    , shutdown = unrealize sb
    }
```

1.4.6 Cardano.BM.Counters

Here the platform is chosen on which we compile this program.
Currently, we mainly support *Linux* with its 'proc' filesystem.

```
{-# LANGUAGE CPP #-}
# if defined (linux_HOST_OS)
# define LINUX
# endif
module Cardano.BM.Counters
  (
    Platform.readCounters
  , diffTimeObserved
  , getMonoClock
  ) where
# ifdef LINUX
import qualified Cardano.BM.Counters.Linux as Platform
# else
import qualified Cardano.BM.Counters.Dummy as Platform
# endif
import Cardano.BM.Counters.Common (getMonoClock)
import Cardano.BM.Data.Aggregated (Measurable (..))
import Cardano.BM.Data.Counter
```

Calculate difference between clocks

```
diffTimeObserved :: CounterState → CounterState → Measurable
diffTimeObserved (CounterState id0 startCounters) (CounterState id1 endCounters) =
    let
      startTime = getMonotonicTime startCounters
      endTime = getMonotonicTime endCounters
    in
    if (id0 ≡ id1)
      then endTime – startTime
      else error "these clocks are not from the same experiment"
  where
    getMonotonicTime counters = case (filter isMonotonicClockCounter counters) of
      [(Counter MonotonicClockTime _ mus)] → mus
      _ → error "A time measurement is missing!"
    isMonotonicClockCounter :: Counter → Bool
    isMonotonicClockCounter = (MonotonicClockTime ≡) ∘ cType
```

1.4.7 Cardano.BM.Counters.Common

Common functions that serve *readCounters* on all platforms.

```
nominalTimeToMicroseconds :: Word64 → Microsecond
nominalTimeToMicroseconds = fromMicroseconds ∘ toInteger ∘ (`div` 1000)
```

Read monotonic clock

```
getMonoClock :: IO [Counter]
getMonoClock = do
  t ← getMonotonicTimeNSec
  return [Counter MonotonicClockTime "monoclock" $ Microseconds (t `div` 1000)]
```

Read GHC RTS statistics

Read counters from GHC's *RTS* (runtime system). The values returned are as per the last GC (garbage collection) run.

```
readRTSStats :: IO [Counter]
readRTSStats = do
    iscollected ← GhcStats.getRTSStatsEnabled
    if iscollected
      then ghcstats
      else return [ ]
  where
    ghcstats :: IO [Counter]
    ghcstats = do
```

```
    -- need to run GC?
    rts ← GhcStats.getRTSStats
    let getrts = ghcval rts
    return [getrts (Bytes ∘ fromIntegral ∘ GhcStats.allocated_bytes, "bytesAllocated")
      ,getrts (Bytes ∘ fromIntegral ∘ GhcStats.max_live_bytes, "liveBytes")
      ,getrts (Bytes ∘ fromIntegral ∘ GhcStats.max_large_objects_bytes, "largeBytes")
      ,getrts (Bytes ∘ fromIntegral ∘ GhcStats.max_compact_bytes, "compactBytes")
      ,getrts (Bytes ∘ fromIntegral ∘ GhcStats.max_slop_bytes, "slopBytes")
      ,getrts (Bytes ∘ fromIntegral ∘ GhcStats.max_mem_in_use_bytes, "usedMemBytes")
      ,getrts (Nanoseconds ∘ fromIntegral ∘ GhcStats.gc_cpu_ns, "gcCpuNs")
      ,getrts (Nanoseconds ∘ fromIntegral ∘ GhcStats.gc_elapsed_ns, "gcElapsedNs")
      ,getrts (Nanoseconds ∘ fromIntegral ∘ GhcStats.cpu_ns, "cpuNs")
      ,getrts (Nanoseconds ∘ fromIntegral ∘ GhcStats.elapsed_ns, "elapsedNs")
      ,getrts (PureI ∘ toInteger ∘ GhcStats.gcs, "gcNum")
      ,getrts (PureI ∘ toInteger ∘ GhcStats.major_gcs, "gcMajorNum")
      ]
  ghcval :: GhcStats.RTSStats → ((GhcStats.RTSStats → Measurable), Text) → Counter
  ghcval s (f, n) = Counter RTSStats n $ (f s)
```

1.4.8 Cardano.BM.Counters.Dummy

This is a dummy definition of *readCounters* on platforms that do not support the 'proc' filesystem from which we would read the counters.

The only supported measurements are monotonic clock time and RTS statistics for now.

```
readCounters :: SubTrace → IO [Counter]
readCounters NoTrace          = return []
readCounters Neutral          = return []
readCounters (TeeTrace _)     = return []
readCounters (FilterTrace _)  = return []
readCounters UntimedTrace     = return []
readCounters DropOpening      = return []
readCounters (ObservableTrace tts) = foldrM (λ(sel,fun) a →
    if any (≡ sel) tts
    then (fun ≫= λxs → return $ a ++ xs)
    else return a)[] selectors
  where
    selectors = [(MonotonicClock, getMonoClock)
      -- , (MemoryStats, readProcStatM)
      -- , (ProcessStats, readProcStats)
        -- , (IOStats, readProcIO)
      ,(GhcRtsStats, readRTSStats)
                  ]
```

1.4.9 Cardano.BM.Counters.Linux

we have to expand the *readMemStats* function
to read full data from *proc*

```
readCounters :: SubTrace → IO [Counter]
readCounters NoTrace          = return [ ]
readCounters Neutral          = return [ ]
readCounters (TeeTrace _)     = return [ ]
readCounters (FilterTrace _) = return [ ]
readCounters UntimedTrace = return [ ]
readCounters DropOpening  = return [ ]
readCounters (ObservableTrace tts) = foldrM (λ(sel,fun) a →
    if any (≡ sel) tts
    then (fun ⋙= λxs → return $ a ++ xs)
    else return a)[ ] selectors
  where
    selectors = [(MonotonicClock,getMonoClock)
      ,(MemoryStats,readProcStatM)
      ,(ProcessStats,readProcStats)
      ,(IOStats,readProcIO)
      ]

pathProc :: FilePath
pathProc = "/proc/"
pathProcStat :: ProcessID → FilePath
pathProcStat pid = pathProc </> (show pid) </> "stat"
pathProcStatM :: ProcessID → FilePath
pathProcStatM pid = pathProc </> (show pid) </> "statm"
pathProcIO :: ProcessID → FilePath
pathProcIO pid = pathProc </> (show pid) </> "io"
```

Reading from a file in /proc/<pid >

```
readProcList :: FilePath → IO [Integer]
readProcList fp = do
  cs ← readFile fp
  return $ map (λs → maybe 0 id $ (readMaybe s :: Maybe Integer)) (words cs)
```

readProcStatM - /proc/<pid >/statm

```
/proc/[pid]/statm
       Provides information about memory usage, measured in pages.  The columns are:
             size       (1) total program size
                           (same as VmSize in /proc/[pid]/status)
             resident   (2) resident set size
                           (same as VmRSS in /proc/[pid]/status)
             shared     (3) number of resident shared pages (i.e., backed by a file)
                           (same as RssFile+RssShmem in /proc/[pid]/status)
             text       (4) text (code)
             lib        (5) library (unused since Linux 2.6; always 0)
             data       (6) data + stack
             dt         (7) dirty pages (unused since Linux 2.6; always 0)
```

```
readProcStatM :: IO [Counter]
readProcStatM = do
    pid ← getProcessID
    ps0 ← readProcList (pathProcStatM pid)
    let ps = zip colnames ps0
        psUseful = filter (("unused" ≠) ∘ fst) ps
    return $ map (λ(n,i) → Counter MemoryCounter n (PureI i)) psUseful
  where
    colnames :: [Text]
    colnames = ["size","resident","shared","text","unused","data","unused"]
```

readProcStats - //proc//<pid >//stat

```
/proc/[pid]/stat
       Status  information about the process.  This is used by ps(1).  It is defined in the kernel source file
       fs/proc/array.c.

       The fields, in order, with their proper scanf(3) format specifiers, are listed below.  Whether  or  not
       certain  of  these  fields  display  valid information is governed by a ptrace access mode
       PTRACE_MODE_READ_FSCREDS | PTRACE_MODE_NOAUDIT check (refer to ptrace(2)).  If the check denies access,
       then the field value is displayed as 0.  The affected fields are indicated with the marking [PT].

       (1) pid  %d
                     The process ID.

       (2) comm  %s
                     The  filename  of  the  executable,  in parentheses.  This is visible whether or not the exe-
                     cutable is swapped out.

       (3) state  %c
                     One of the following characters, indicating process state:

                     R  Running

                     S  Sleeping in an interruptible wait

                     D  Waiting in uninterruptible disk sleep

                     Z  Zombie

                     T  Stopped (on a signal) or (before Linux 2.6.33) trace stopped

                     t  Tracing stop (Linux 2.6.33 onward)

                     W  Paging (only before Linux 2.6.0)

                     X  Dead (from Linux 2.6.0 onward)

                     x  Dead (Linux 2.6.33 to 3.13 only)

                     K  Wakekill (Linux 2.6.33 to 3.13 only)

                     W  Waking (Linux 2.6.33 to 3.13 only)

                     P  Parked (Linux 3.9 to 3.13 only)

       (4) ppid  %d
                     The PID of the parent of this process.

       (5) pgrp  %d
                     The process group ID of the process.
```

```
(6) session  %d
              The session ID of the process.

(7) tty_nr  %d
              The controlling terminal of the process.  (The minor device number is contained in the combi-
              nation of bits 31 to 20 and 7 to 0; the major device number is in bits 15 to 8.)

(8) tpgid  %d
              The ID of the foreground process group of the controlling terminal of the process.

(9) flags  %u
              The  kernel  flags  word of the process.  For bit meanings, see the PF_* defines in the Linux
              kernel source file include/linux/sched.h.  Details depend on the kernel version.

              The format for this field was %lu before Linux 2.6.

(10) minflt  %lu
              The number of minor faults the process has made which have not required loading a memory page
              from disk.

(11) cminflt  %lu
              The number of minor faults that the process's waited-for children have made.

(12) majflt  %lu
              The  number  of  major  faults the process has made which have required loading a memory page
              from disk.

(13) cmajflt  %lu
              The number of major faults that the process's waited-for children have made.

(14) utime  %lu
              Amount of time that this process has been scheduled in user mode,  measured  in  clock  ticks
              (divide by sysconf(_SC_CLK_TCK)).  This includes guest time, guest_time (time spent running a
              virtual CPU, see below), so that applications that are not aware of the guest time  field  do
              not lose that time from their calculations.

(15) stime  %lu
              Amount  of  time that this process has been scheduled in kernel mode, measured in clock ticks
              (divide by sysconf(_SC_CLK_TCK)).

(16) cutime  %ld
              Amount of time that this process's waited-for children have been scheduled in user mode, mea-
              sured  in  clock ticks (divide by sysconf(_SC_CLK_TCK)).  (See also times(2).)  This includes
              guest time, cguest_time (time spent running a virtual CPU, see below).

(17) cstime  %ld
              Amount of time that this process's waited-for children have been scheduled  in  kernel  mode,
              measured in clock ticks (divide by sysconf(_SC_CLK_TCK)).

(18) priority  %ld
              (Explanation  for  Linux  2.6)  For  processes  running a real-time scheduling policy (policy
              below; see sched_setscheduler(2)), this is the negated scheduling priority, minus  one;  that
              is,  a  number  in  the range -2 to -100, corresponding to real-time priorities 1 to 99.  For
              processes running under a non-real-time scheduling policy, this is the raw nice  value  (set-
              priority(2))  as  represented in the kernel.  The kernel stores nice values as numbers in the
              range 0 (high) to 39 (low), corresponding to the user-visible nice range of -20 to 19.

(19) nice  %ld
              The nice value (see setpriority(2)), a value in the range 19 (low priority) to -20 (high pri-
              ority).

(20) num_threads  %ld
              Number of threads in this process (since Linux 2.6).  Before kernel 2.6, this field was  hard
              coded to 0 as a placeholder for an earlier removed field.

(21) itrealvalue  %ld
              The  time in jiffies before the next SIGALRM is sent to the process due to an interval timer.
              Since kernel 2.6.17, this field is no longer maintained, and is hard coded as 0.
```

(22) starttime %llu
The time the process started after system boot. In kernels before Linux 2.6, this value was expressed in jiffies. Since Linux 2.6, the value is expressed in clock ticks (divide by sysconf(_SC_CLK_TCK)).

The format for this field was %lu before Linux 2.6.

(23) vsize %lu
Virtual memory size in bytes.

(24) rss %ld
Resident Set Size: number of pages the process has in real memory. This is just the pages which count toward text, data, or stack space. This does not include pages which have not been demand-loaded in, or which are swapped out.

(25) rsslim %lu
Current soft limit in bytes on the rss of the process; see the description of RLIMIT_RSS in getrlimit(2).

(26) startcode %lu [PT]
The address above which program text can run.

(27) endcode %lu [PT]
The address below which program text can run.

(28) startstack %lu [PT]
The address of the start (i.e., bottom) of the stack.

(29) kstkesp %lu [PT]
The current value of ESP (stack pointer), as found in the kernel stack page for the process.

(30) kstkeip %lu [PT]
The current EIP (instruction pointer).

(31) signal %lu
The bitmap of pending signals, displayed as a decimal number. Obsolete, because it does not provide information on real-time signals; use /proc/[pid]/status instead.

(32) blocked %lu
The bitmap of blocked signals, displayed as a decimal number. Obsolete, because it does not provide information on real-time signals; use /proc/[pid]/status instead.

(33) sigignore %lu
The bitmap of ignored signals, displayed as a decimal number. Obsolete, because it does not provide information on real-time signals; use /proc/[pid]/status instead.

(34) sigcatch %lu
The bitmap of caught signals, displayed as a decimal number. Obsolete, because it does not provide information on real-time signals; use /proc/[pid]/status instead.

(35) wchan %lu [PT]
This is the "channel" in which the process is waiting. It is the address of a location in the kernel where the process is sleeping. The corresponding symbolic name can be found in /proc/[pid]/wchan.

(36) nswap %lu
Number of pages swapped (not maintained).

(37) cnswap %lu
Cumulative nswap for child processes (not maintained).

(38) exit_signal %d (since Linux 2.1.22)
Signal to be sent to parent when we die.

(39) processor %d (since Linux 2.2.8)
CPU number last executed on.

```
(40) rt_priority  %u  (since Linux 2.5.19)
             Real-time  scheduling priority, a number in the range 1 to 99 for processes scheduled under a
             real-time policy, or 0, for non-real-time processes (see sched_setscheduler(2)).

(41) policy  %u  (since Linux 2.5.19)
             Scheduling policy  (see  sched_setscheduler(2)).  Decode  using  the  SCHED_*  constants  in
             linux/sched.h.

             The format for this field was %lu before Linux 2.6.22.

(42) delayacct_blkio_ticks  %llu  (since Linux 2.6.18)
             Aggregated block I/O delays, measured in clock ticks (centiseconds).

(43) guest_time  %lu  (since Linux 2.6.24)
             Guest  time  of  the process (time spent running a virtual CPU for a guest operating system),
             measured in clock ticks (divide by sysconf(_SC_CLK_TCK)).

(44) cguest_time  %ld  (since Linux 2.6.24)
             Guest  time  of  the  process's  children,  measured  in  clock  ticks  (divide  by
             sysconf(_SC_CLK_TCK)).

(45) start_data  %lu  (since Linux 3.3)  [PT]
             Address above which program initialized and uninitialized (BSS) data are placed.

(46) end_data  %lu  (since Linux 3.3)  [PT]
             Address below which program initialized and uninitialized (BSS) data are placed.

(47) start_brk  %lu  (since Linux 3.3)  [PT]
             Address above which program heap can be expanded with brk(2).

(48) arg_start  %lu  (since Linux 3.5)  [PT]
             Address above which program command-line arguments (argv) are placed.

(49) arg_end  %lu  (since Linux 3.5)  [PT]
             Address below program command-line arguments (argv) are placed.

(50) env_start  %lu  (since Linux 3.5)  [PT]
             Address above which program environment is placed.

(51) env_end  %lu  (since Linux 3.5)  [PT]
             Address below which program environment is placed.

(52) exit_code  %d  (since Linux 3.5)  [PT]
             The thread's exit status in the form reported by waitpid(2).
```

```
readProcStats :: IO [Counter]
readProcStats = do
    pid ← getProcessID
    ps0 ← readProcList (pathProcStat pid)
    let ps = zip colnames ps0
        psUseful = filter ((("unused" ≢) ∘ fst) ps
    return $ map (λ(n,i) → Counter StatInfo n (PureI i)) psUseful
  where
    colnames :: [Text]
    colnames = ["pid","unused","unused","ppid","pgrp","session","ttynr","tpgid","flags","minfl

      ,"envend","exitcode"
      ]
```

readProcIO - //proc//<pid >//io

```
/proc/[pid]/io (since kernel 2.6.20)
       This file contains I/O statistics for the process, for example:

              # cat /proc/3828/io
              rchar: 323934931
              wchar: 323929600
              syscr: 632687
              syscw: 632675
              read_bytes: 0
              write_bytes: 323932160
              cancelled_write_bytes: 0

       The fields are as follows:

       rchar: characters read
              The number of bytes which this task has caused to be read from storage.  This is simply the  sum
              of bytes which this process passed to read(2) and similar system calls.  It includes things such
              as terminal I/O and is unaffected by whether or not actual physical disk I/O was  required  (the
              read might have been satisfied from pagecache).

       wchar: characters written
              The  number  of bytes which this task has caused, or shall cause to be written to disk.  Similar
              caveats apply here as with rchar.

       syscr: read syscalls
              Attempt to count the number of read I/O operations-that is, system calls  such  as  read(2)  and
              pread(2).

       syscw: write syscalls
              Attempt  to  count the number of write I/O operations-that is, system calls such as write(2) and
              pwrite(2).

       read_bytes: bytes read
              Attempt to count the number of bytes which this process really did cause to be fetched from  the
              storage layer.  This is accurate for block-backed filesystems.

       write_bytes: bytes written
              Attempt to count the number of bytes which this process caused to be sent to the storage layer.

       cancelled_write_bytes:
              The  big  inaccuracy  here  is truncate.  If a process writes 1MB to a file and then deletes the
              file, it will in fact perform no writeout.  But it will have been accounted as having caused 1MB
              of  write.   In other words: this field represents the number of bytes which this process caused
              to not happen, by truncating pagecache.  A task can cause "negative"  I/O  too.   If  this  task
              truncates  some  dirty  pagecache,  some  I/O  which another task has been accounted for (in its
              write\_bytes) will not be happening.

       Note: In the current implementation, things are a bit racy  on  32-bit  systems:  if  process  A  reads
       process  B's  /proc/[pid]/io  while process B is updating one of these 64-bit counters, process A could
       see an intermediate result.

       Permission to access this file is governed by a ptrace access mode PTRACE\_MODE\_READ\_FSCREDS check;  see
       ptrace(2).
```

```

readProcIO = do
    pid ← getProcessID
    ps0 ← readProcList (pathProcIO pid)
    let ps = zip3 colnames ps0 units
    return $ map (λ(n,i,u) → Counter IOCounter n (u i)) ps
  where
    colnames :: [Text]
```

```
colnames = ["rchar","wchar","syscr","syscw","rbytes","wbytes","cxwbytes"]
units = [Bytes ∘ fromInteger,Bytes ∘ fromInteger,PureI,PureI,Bytes ∘ fromInteger,Bytes ∘ fromInteger,Bytes
```

1.4.10 Cardano.BM.Data.Aggregated

Measurable

A Measurable may consist of different types of values. Time measurements are strict, so are *Bytes* which are externally measured. The real or integral numeric values are lazily linked, so we can decide later to drop them.

```
data Measurable = Microseconds {-# UNPACK #-} !Word64
  | Nanoseconds {-# UNPACK #-} !Word64
  | Seconds {-# UNPACK #-} !Word64
  | Bytes {-# UNPACK #-} !Word64
  | PureD Double
  | PureI Integer
  deriving (Eq,Ord,Generic,ToJSON)
```

Measurable can be transformed to an integral value.

```
getInteger :: Measurable → Integer
getInteger (Microseconds a) = toInteger a
getInteger (Nanoseconds a) = toInteger a
getInteger (Seconds a) = toInteger a
getInteger (Bytes a) = toInteger a
getInteger (PureI a) = a
getInteger (PureD a) = round a
```

Measurable can be transformed to a rational value.

```
getDouble :: Measurable → Double
getDouble (Microseconds a) = fromIntegral a
getDouble (Nanoseconds a) = fromIntegral a
getDouble (Seconds a) = fromIntegral a
getDouble (Bytes a) = fromIntegral a
getDouble (PureI a) = fromInteger a
getDouble (PureD a) = a
```

It is a numerical value, thus supports functions to operate on numbers.

```
instance Num Measurable where
  (+) (Microseconds a) (Microseconds b) = Microseconds (a + b)
  (+) (Nanoseconds a) (Nanoseconds b) = Nanoseconds (a + b)
  (+) (Seconds a) (Seconds b) = Seconds (a + b)
  (+) (Bytes a) (Bytes b) = Bytes (a + b)
  (+) (PureI a) (PureI b) = PureI (a + b)
  (+) (PureD a) (PureD b) = PureD (a + b)
  (+) _ _ = error "Trying to add values with different units"
```

```
  (*) (Microseconds a) (Microseconds b) = Microseconds (a * b)
  (*) (Nanoseconds a)  (Nanoseconds b)  = Nanoseconds (a * b)
  (*) (Seconds a)      (Seconds b)      = Seconds     (a * b)
  (*) (Bytes a)        (Bytes b)        = Bytes       (a * b)

  show (AggregatedEWMA a) = show a
```

1.4.11 Cardano.BM.Data.Backend

Accepts a NamedLogItem

Instances of this type class accept a NamedLogItem and deal with it.

```
class IsEffectuator t where
  effectuate :: t → NamedLogItem → IO ()
  effectuatefrom :: forall s ∘ (IsEffectuator s) ⇒ t → NamedLogItem → s → IO ()
  default effectuatefrom :: forall s ∘ (IsEffectuator s) ⇒ t → NamedLogItem → s → IO ()
  effectuatefrom t nli _ = effectuate t nli
```

Declaration of a Backend

A backend is life-cycle managed, thus can be *realize*d and *unrealize*d.

```
class (IsEffectuator t) ⇒ IsBackend t where
  typeof     :: t → BackendKind
  realize    :: Configuration → IO t
  realizefrom :: forall s ∘ (IsEffectuator s) ⇒ Trace IO → s → IO t
  default realizefrom :: forall s ∘ (IsEffectuator s) ⇒ Trace IO → s → IO t
  realizefrom (ctx, _) _ = realize (configuration ctx)
  unrealize :: t → IO ()
```

Backend

This data structure for a backend defines its behaviour as an IsEffectuator when processing an incoming message, and as an IsBackend for unrealizing the backend.

```
data Backend = MkBackend
  {bEffectuate :: NamedLogItem → IO ()
  ,bUnrealize :: IO ()
  }
```

1.4.12 Cardano.BM.Data.Configuration

Data structure to help parsing configuration files.

Representation

```
type Port = Int
data Representation = Representation
  {minSeverity     :: Severity
  ,rotation        :: RotationParameters
  ,setupScribes    :: [ScribeDefinition]
  ,defaultScribes  :: [(ScribeKind, Text)]
  ,setupBackends   :: [BackendKind]
  ,defaultBackends :: [BackendKind]
```

```
  , hasEKG      :: Maybe Port
  , hasGUI      :: Maybe Port
  , options     :: HM.HashMap Text Object
  }
  deriving (Generic, Show, ToJSON, FromJSON)
```

parseRepresentation

```
parseRepresentation :: FilePath → IO Representation
parseRepresentation fp = do
  repr :: Representation ← decodeFileThrow fp
  return $ implicit_fill_representation repr
```

after parsing the configuration representation we implicitly correct it.

```
implicit_fill_representation :: Representation → Representation
implicit_fill_representation =
    remove_ekgview_if_not_defined ∘
    filter_duplicates_from_backends ∘
    filter_duplicates_from_scribes ∘
    union_setup_and_usage_backends ∘
    add_ekgview_if_port_defined ∘
    add_katip_if_any_scribes
  where
    filter_duplicates_from_backends r =
      r {setupBackends = mkUniq $ setupBackends r}
    filter_duplicates_from_scribes r =
      r {setupScribes = mkUniq $ setupScribes r}
    union_setup_and_usage_backends r =
      r {setupBackends = setupBackends r <> defaultBackends r}
    remove_ekgview_if_not_defined r =
      case hasEKG r of
      Nothing → r {defaultBackends = filter (λbk → bk ≢ EKGViewBK) (defaultBackends r)
        , setupBackends = filter (λbk → bk ≢ EKGViewBK) (setupBackends r)
        }
      Just _ → r
    add_ekgview_if_port_defined r =
      case hasEKG r of
      Nothing → r
      Just _ → r {setupBackends = setupBackends r <> [EKGViewBK]}
    add_katip_if_any_scribes r =
      if (any ¬ [null $ setupScribes r, null $ defaultScribes r])
      then r {setupBackends = setupBackends r <> [KatipBK]}
      else r
    mkUniq :: Ord a ⇒ [a] → [a]
    mkUniq = Set.toList ∘ Set.fromList
```

1.4.13 Cardano.BM.Data.Counter

Counter

```
data Counter = Counter
        {cType  :: CounterType
        ,cName :: Text
        ,cValue :: Measurable
        }
        deriving (Eq, Show, Generic, ToJSON)
data CounterType = MonotonicClockTime
  | MemoryCounter
  | StatInfo
  | IOCounter
  | CpuCounter
  | RTSStats
    deriving (Eq, Show, Generic, ToJSON)
instance ToJSON Microsecond where
  toJSON = toJSON ∘ toMicroseconds
  toEncoding = toEncoding ∘ toMicroseconds
```

Names of counters

```
nameCounter :: Counter → Text
nameCounter (Counter MonotonicClockTime _ _) = "Time-interval"
nameCounter (Counter MemoryCounter _ _) = "Mem"
nameCounter (Counter StatInfo          _ _) = "Stat"
nameCounter (Counter IOCounter         _ _) = "IO"
nameCounter (Counter CpuCounter        _ _) = "Cpu"
nameCounter (Counter RTSStats          _ _) = "RTS"
```

CounterState

```
data CounterState = CounterState {
  csIdentifier :: Unique
  ,csCounters :: [Counter]
  }
  deriving (Generic, ToJSON)
instance ToJSON Unique where
  toJSON = toJSON ∘ hashUnique
  toEncoding = toEncoding ∘ hashUnique
instance Show CounterState where
  show cs = (show ∘ hashUnique) (csIdentifier cs)
    <> "  =>  " <> (show $ csCounters cs)
```

Difference between counters

```
diffCounters :: [Counter] → [Counter] → [Counter]
diffCounters openings closings =
    getCountersDiff openings closings
  where
    getCountersDiff :: [Counter]
                    → [Counter]

    getCountersDiff as bs =
      let
        getName counter = nameCounter counter <> cName counter
        asNames = map getName as
        aPairs = zip asNames as
        bsNames = map getName bs
        bs' = zip bsNames bs
        bPairs = HM.fromList bs'
      in
        catMaybes $ (flip map) aPairs $ λ(name, Counter _ _ startValue) →
          case HM.lookup name bPairs of
            Nothing      → Nothing
            Just counter → let endValue = cValue counter
                           in Just counter {cValue = endValue – startValue}
```

1.4.14 Cardano.BM.Data.LogItem

LoggerName

A LoggerName has currently type *Text*.

```
type LoggerName = Text
```

NamedLogItem

```
type NamedLogItem = LogNamed LogObject
```

LogNamed

A LogNamed contains of a context name and some log item.

```
data LogNamed item = LogNamed
  {lnName :: LoggerName
  ,lnItem :: item
  } deriving (Show)
deriving instance Generic item ⇒ Generic (LogNamed item)
deriving instance (ToJSON item, Generic item) ⇒ ToJSON (LogNamed item)
```

Logging of outcomes with LogObject

```
data LogObject = LogObject LOMeta LOContent
  deriving (Generic, Show, ToJSON)
```

Meta data for a LogObject:

```
data LOMeta = LOMeta {
  tstamp :: {-# UNPACK #-} !UTCTime
  ,tid :: {-# UNPACK #-} !ThreadId
  }
  deriving (Show)
instance ToJSON LOMeta where
  toJSON (LOMeta _tstamp _tid) =
    object ["tstamp" .= _tstamp, "tid" .= show _tid]
mkLOMeta :: IO LOMeta
mkLOMeta =
  LOMeta <$> getCurrentTime
    <*> myThreadId
```

Payload of a LogObject:

```
data LOContent = LogMessage LogItem
  | LogValue Text Measurable
  | ObserveOpen CounterState
  | ObserveDiff CounterState
  | ObserveClose CounterState
  | AggregatedMessage [(Text, Aggregated)]
  | KillPill
    deriving (Generic, Show, ToJSON)
```

LogItem

TODO liPayload :: *ToObject*

```
data LogItem = LogItem
  {liSelection :: LogSelection
  ,liSeverity :: Severity
  ,liPayload :: Text-- TODO should become ToObject
  } deriving (Show, Generic, ToJSON)

data LogSelection =
  Public  -- only to public logs.
  | PublicUnsafe-- only to public logs, not console.
  | Private-- only to private logs.
  | Both  -- to public and private logs.
  deriving (Show, Generic, ToJSON, FromJSON)
```

1.4.15 Cardano.BM.Data.Observable

ObservableInstance

```
data ObservableInstance = MonotonicClock
  | MemoryStats
  | ProcessStats
  | IOStats
  | GhcRtsStats
    deriving (Generic, Eq, Ord, Show, FromJSON, ToJSON, Read)
```

1.4.16 Cardano.BM.Data.Output

OutputKind

```
data OutputKind = TVarList (STM.TVar [LogObject])
  | TVarListNamed (STM.TVar [LogNamed LogObject])
  deriving (Eq)
```

ScribeKind

This identifies katip's scribes by type.

```
data ScribeKind = FileTextSK
  | FileJsonSK
  | StdoutSK
  | StderrSK
  deriving (Generic, Eq, Ord, Show, FromJSON, ToJSON)
```

ScribeId

A scribe is identified by ScribeKind *x Filename*

```
type ScribeId = Text-- (ScribeKind ::  Filename)
```

ScribeDefinition

This identifies katip's scribes by type.

```
data ScribeDefinition = ScribeDefinition
  {scKind  :: ScribeKind
  ,scName :: Text
  ,scRotation :: Maybe RotationParameters
  }
  deriving (Generic, Eq, Ord, Show, FromJSON, ToJSON)
```

1.4.17 Cardano.BM.Data.Severity

Severity

The intended meaning of severity codes:

Debug *detailled information about values and decision flow* Info general information of events; progressing properly Notice *needs attention;something ¬ progressing properly* Warning may continue into an error condition if continued Error *unexpected set* **of** *event or condition occured* Critical error condition causing degrade of operation Alert *a subsystem is no longer operating correctly,likely requires manual* at this point, the system can never progress without additional intervention

We were informed by the *Syslog* taxonomy: https://en.wikipedia.org/wiki/Syslog#Severity_level

```
data Severity = Debug
  | Info
  | Notice
  | Warning
  | Error
  | Critical
  | Alert
  | Emergency
    deriving (Show, Eq, Ord, Generic, ToJSON, Read)
instance FromJSON Severity where
  parseJSON = withText "severity" $ λcase
    "Debug"     → pure Debug
    "Info"      → pure Info
    "Notice"    → pure Notice
    "Warning"   → pure Warning
    "Error"     → pure Error
    "Critical"  → pure Critical
    "Alert"     → pure Alert
    "Emergency" → pure Emergency
    _           → pure Info-- catch all
```

1.4.18 Cardano.BM.Data.SubTrace

SubTrace

```
data NameSelector = Exact Text | StartsWith Text | EndsWith Text | Contains Text
                    deriving (Generic, Show, FromJSON, ToJSON, Read, Eq)
data DropName     = Drop NameSelector
                    deriving (Generic, Show, FromJSON, ToJSON, Read, Eq)
data UnhideNames = Unhide [NameSelector]
                    deriving (Generic, Show, FromJSON, ToJSON, Read, Eq)
data SubTrace = Neutral
  | UntimedTrace
  | NoTrace
  | TeeTrace LoggerName
  | FilterTrace [(DropName, UnhideNames)]
```

```
  | DropOpening
  | ObservableTrace [ObservableInstance]
    deriving (Generic, Show, FromJSON, ToJSON, Read, Eq)
```

1.4.19 Cardano.BM.Data.Trace

Trace

A Trace consists of a TraceContext and a TraceNamed in *m*.

```
type Trace m = (TraceContext, TraceNamed m)
```

TraceNamed

A TraceNamed is a specialized Contravariant of type NamedLogItem, a LogNamed with payload LogObject.

```
type TraceNamed m = BaseTrace m (NamedLogItem)
```

TraceContext

We keep the context's name and a reference to the Configuration in the TraceContext.

```
data TraceContext = TraceContext
  {loggerName :: LoggerName
  ,configuration :: Configuration
  ,tracetype     :: SubTrace
  ,minSeverity :: Severity
  ,shutdown    :: IO ()
  }
```

1.4.20 Cardano.BM.Configuration

see Cardano.BM.Configuration.Model for the implementation.

```
getOptionOrDefault :: CM.Configuration → Text → Text → IO (Text)
getOptionOrDefault cg name def = do
  opt ← CM.getOption cg name
  case opt of
    Nothing → return def
    Just o → return o
```

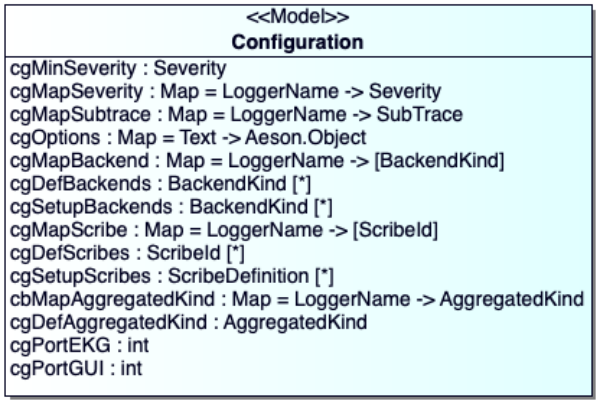

Figure 1.4: Configuration model

1.4.21 Cardano.BM.Configuration.Model

Configuration.Model

```
type ConfigurationMVar = MVar ConfigurationInternal
newtype Configuration = Configuration
  {getCG :: ConfigurationMVar}
-- Our internal state; see -"Configuration model"-
data ConfigurationInternal = ConfigurationInternal
  {cgMinSeverity      :: Severity
  -- minimum severity level of every object that will be output
  ,cgMapSeverity      :: HM.HashMap LoggerName Severity
  -- severity filter per loggername
  ,cgMapSubtrace      :: HM.HashMap LoggerName SubTrace
  -- type of trace per loggername
  ,cgOptions          :: HM.HashMap Text Object
  -- options needed for tracing, logging and monitoring
  ,cgMapBackend       :: HM.HashMap LoggerName [BackendKind]
  -- backends that will be used for the specific loggername
  ,cgDefBackendKs     :: [BackendKind]
  -- backends that will be used if a set of backends for the
  -- specific loggername is not set
  ,cgSetupBackends    :: [BackendKind]
  -- backends to setup; every backend to be used must have
  -- been declared here
  ,cgMapScribe        :: HM.HashMap LoggerName [ScribeId]
  -- katip scribes that will be used for the specific loggername
  ,cgMapScribeCache   :: HM.HashMap LoggerName [ScribeId]
  -- map to cache info of the cgMapScribe
  ,cgDefScribes       :: [ScribeId]
  -- katip scribes that will be used if a set of scribes for the
```

```
  -- specific loggername is not set
  ,cgSetupScribes     :: [ScribeDefinition]
  -- katip scribes to setup; every scribe to be used must have
  -- been declared here
  ,cgMapAggregatedKind :: HM.HashMap LoggerName AggregatedKind
  -- kind of Aggregated that will be used for the specific loggername
  ,cgDefAggregatedKind :: AggregatedKind
  -- kind of Aggregated that will be used if a set of scribes for the
  -- specific loggername is not set
  ,cgPortEKG          :: Int
  -- port for EKG server
  ,cgPortGUI          :: Int
  -- port for changes at runtime (NOT IMPLEMENTED YET)
  } deriving (Show, Eq)
```

Backends configured in the Switchboard

For a given context name return the list of backends configured, or, in case no such configuration exists, return the default backends.

```
getBackends :: Configuration → LoggerName → IO [BackendKind]
getBackends configuration name =
  withMVar (getCG configuration) $ λcg → do
    let outs = HM.lookup name (cgMapBackend cg)
    case outs of
      Nothing → do
        return (cgDefBackendKs cg)
      Just os → return os

getDefaultBackends :: Configuration → IO [BackendKind]
getDefaultBackends configuration =
  withMVar (getCG configuration) $ λcg → do
    return (cgDefBackendKs cg)

setDefaultBackends :: Configuration → [BackendKind] → IO ()
setDefaultBackends configuration bes = do
  cg ← takeMVar (getCG configuration)
  putMVar (getCG configuration) $ cg {cgDefBackendKs = bes}

setBackends :: Configuration → LoggerName → Maybe [BackendKind] → IO ()
setBackends configuration name be = do
  cg ← takeMVar (getCG configuration)
  putMVar (getCG configuration) $ cg {cgMapBackend = HM.alter (\_ → be) name (cgMapBackend cg)}
```

Backends to be setup by the Switchboard

Defines the list of Backends that need to be setup by the Switchboard.

```
setSetupBackends :: Configuration → [BackendKind] → IO ()
setSetupBackends configuration bes = do
```

```
    cg ← takeMVar (getCG configuration)
    putMVar (getCG configuration) $ cg {cgSetupBackends = bes}
getSetupBackends :: Configuration → IO [BackendKind]
getSetupBackends configuration =
    withMVar (getCG configuration) $ λcg →
        return $ cgSetupBackends cg
```

Scribes configured in the Log backend

For a given context name return the list of scribes to output to, or, in case no such configuration exists, return the default scribes to use.

```
getScribes :: Configuration → LoggerName → IO [ScribeId]
getScribes configuration name = do
    (updateCache, scribes) ← withMVar (getCG configuration) $ λcg → do
        let defs = cgDefScribes cg

setDefaultScribes configuration scs = do
    cg ← takeMVar (getCG configuration)
    putMVar (getCG configuration) $ cg {cgDefScribes = scs}
```

Scribes to be setup in the Log backend

Defines the list of *Scribe*s that need to be setup in the Log backend.

```
setSetupScribes :: Configuration → [ScribeDefinition] → IO ()
setSetupScribes configuration sds = do
  cg ← takeMVar (getCG configuration)
  putMVar (getCG configuration) $ cg {cgSetupScribes = sds}
getSetupScribes :: Configuration → IO [ScribeDefinition]
getSetupScribes configuration =
  withMVar (getCG configuration) $ λcg → do
    return $ cgSetupScribes cg
```

AggregatedKind **to define the type of measurement**

For a given context name return its *AggregatedKind* or in case no such configuration exists, return the default *AggregatedKind* to use.

```
getAggregatedKind :: Configuration → LoggerName → IO AggregatedKind
getAggregatedKind configuration name =
  withMVar (getCG configuration) $ λcg → do
    let outs = HM.lookup name (cgMapAggregatedKind cg)
    case outs of
      Nothing → do
        return (cgDefAggregatedKind cg)
      Just os → return $ os
setDefaultAggregatedKind :: Configuration → AggregatedKind → IO ()
setDefaultAggregatedKind configuration defAK = do
  cg ← takeMVar (getCG configuration)
  putMVar (getCG configuration) $ cg {cgDefAggregatedKind = defAK}
setAggregatedKind :: Configuration → LoggerName → Maybe AggregatedKind → IO ()
setAggregatedKind configuration name ak = do
  cg ← takeMVar (getCG configuration)
  putMVar (getCG configuration) $ cg {cgMapAggregatedKind = HM.alter (\_ → ak) name (cgMapAggregatedKi
```

Access port numbers of EKG, GUI

```
getEKGport :: Configuration → IO Int
getEKGport configuration =
  withMVar (getCG configuration) $ λcg → do
    return $ cgPortEKG cg
setEKGport :: Configuration → Int → IO ()
setEKGport configuration port = do
  cg ← takeMVar (getCG configuration)
  putMVar (getCG configuration) $ cg {cgPortEKG = port}
getGUIport :: Configuration → IO Int
getGUIport configuration =
  withMVar (getCG configuration) $ λcg → do
    return $ cgPortGUI cg
setGUIport :: Configuration → Int → IO ()
setGUIport configuration port = do
  cg ← takeMVar (getCG configuration)
  putMVar (getCG configuration) $ cg {cgPortGUI = port}
```

Options

```
getOption :: Configuration → Text → IO (Maybe Text)
getOption configuration name = do
  withMVar (getCG configuration) $ λcg →
    case HM.lookup name (cgOptions cg) of
      Nothing → return Nothing
      Just o → return $ Just $ pack $ show o
```

Global setting of minimum severity

```
minSeverity :: Configuration → IO Severity
minSeverity configuration = withMVar (getCG configuration) $ λcg →
  return $ cgMinSeverity cg
setMinSeverity :: Configuration → Severity → IO ()
setMinSeverity configuration sev = do
  cg ← takeMVar (getCG configuration)
  putMVar (getCG configuration) $ cg {cgMinSeverity = sev}
```

Relation of context name to minimum severity

```
inspectSeverity :: Configuration → Text → IO (Maybe Severity)
inspectSeverity configuration name = do
  withMVar (getCG configuration) $ λcg →
```

```
    return $ HM.lookup name (cgMapSeverity cg)
setSeverity :: Configuration → Text → Maybe Severity → IO ()
setSeverity configuration name sev = do
  cg ← takeMVar (getCG configuration)
  putMVar (getCG configuration) $ cg {cgMapSeverity = HM.alter (\_ → sev) name (cgMapSeverity cg)}
```

Relation of context name to SubTrace

A new context may contain a different type of Trace. The function appendName (Enter new named context) will look up the SubTrace for the context's name.

```
findSubTrace :: Configuration → Text → IO (Maybe SubTrace)
findSubTrace configuration name = do
  withMVar (getCG configuration) $ λcg →
    return $ HM.lookup name (cgMapSubtrace cg)
setSubTrace :: Configuration → Text → Maybe SubTrace → IO ()
setSubTrace configuration name trafo = do
  cg ← takeMVar (getCG configuration)
  putMVar (getCG configuration) $ cg {cgMapSubtrace = HM.alter (\_ → trafo) name (cgMapSubtrace cg)}
```

Parse configuration from file

Parse the configuration into an internal representation first. Then, fill in Configuration after refinement.

```
setup :: FilePath → IO Configuration
setup fp = do
    r ← R.parseRepresentation fp
    setupFromRepresentation r
setupFromRepresentation :: R.Representation → IO Configuration

1.4.22 Cardano.BM.Output.Switchboard

Switchboard

```
type SwitchboardMVar = MVar SwitchboardInternal
newtype Switchboard = Switchboard
  {getSB :: SwitchboardMVar}
data SwitchboardInternal = SwitchboardInternal
  {sbQueue :: TBQ.TBQueue NamedLogItem
  ,sbDispatch :: Async.Async ()
  }
```

Trace that forwards to the Switchboard

Every Trace ends in the Switchboard which then takes care of dispatching the messages to outputs

```
mainTrace :: Switchboard → TraceNamed IO
mainTrace sb = BaseTrace.BaseTrace $ Op $ λlognamed → do
  effectuate sb lognamed
```

Process incoming messages

Incoming messages are put into the queue, and then processed by the dispatcher.
The queue is initialized and the message dispatcher launched.

```
instance IsEffectuator Switchboard where
  effectuate switchboard item = do
```

```
    let writequeue :: TBQ.TBQueue NamedLogItem → NamedLogItem → IO ()
        writequeue q i = do
          nocapacity ← atomically $ TBQ.isFullTBQueue q
          if nocapacity
          then return ()
          else atomically $ TBQ.writeTBQueue q i
    withMVar (getSB switchboard) $ λsb →
      writequeue (sbQueue sb) item
```

Switchboard implements Backend functions

Switchboard is an Declaration of a Backend

```
instance IsBackend Switchboard where
  typeof _ = SwitchboardBK
  realize cfg =
    let spawnDispatcher
          :: Configuration
          → [(BackendKind, Backend)]
          → TBQ.TBQueue NamedLogItem
          → IO (Async.Async ())
        spawnDispatcher config backends queue =
          let sendMessage nli befilter = do
                selectedBackends ← getBackends config (lnName nli)
                let selBEs = befilter selectedBackends
                forM_ backends $ λ(bek, be) →
                  when (bek ∈ selBEs) (bEffectuate be $ nli)
              qProc = do
                nli ← atomically $ TBQ.readTBQueue queue
                case lnItem nli of
                  LogObject _ KillPill →
                    forM_ backends (λ(_, be) → bUnrealize be)
                  LogObject _ (AggregatedMessage _) → do
                    sendMessage nli (filter (≢ AggregationBK))

          Trace.traceNamedObject trace' logvalue
          qProc
        Nothing → return ()-- stop here
```

Interactive testing EKGView

```
test :: IO ()
test = do
  c ← Cardano.BM.Setup.setupTrace (Left "test/config.yaml") "ekg"
  ev ← Cardano.BM.Output ∘ EKGView.realize c
  effectuate ev $ LogNamed "test.questions" (LogValue "answer" 42)
  effectuate ev $ LogNamed "test.monitor023" (LogMessage (LogItem Public Warning "!!!! ALARM !!!!"
```

1.4.25 Cardano.BM.Output.Aggregation

Internal representation

```
type AggregationMVar = MVar AggregationInternal
newtype Aggregation = Aggregation
  {getAg :: AggregationMVar}
data AggregationInternal = AggregationInternal
  {agQueue :: TBQ.TBQueue (Maybe NamedLogItem)
  ,agDispatch :: Async.Async ()
  }
```

Relation from context name to aggregated statistics

We keep the aggregated values (Aggregated) for a named context in a *HashMap*.

```
type AggregationMap = HM.HashMap Text AggregatedExpanded
```

Info for Aggregated operations

Apart from the Aggregated we keep some valuable info regarding to them; such as when was the last time it was sent.

```
type Timestamp = Word64
data AggregatedExpanded = AggregatedExpanded
  {aeAggregated :: !Aggregated
  ,aeResetAfter :: !(Maybe Word64)
  ,aeLastSent ::  {-# UNPACK #-}  !Timestamp
  }
```

Aggregation implements *effectuate*

Aggregation is an Accepts a NamedLogItem Enter the log item into the Aggregation queue.

```
instance IsEffectuator Aggregation where
  effectuate agg item = do
    ag ← readMVar (getAg agg)
    nocapacity ← atomically $ TBQ.isFullTBQueue (agQueue ag)
    if nocapacity
    then return ()
    else atomically $! TBQ.writeTBQueue (agQueue ag) $ Just item
```

Aggregation implements Backend functions

Aggregation is an Declaration of a Backend

```
instance IsBackend Aggregation where
  typeof _ = AggregationBK
  realize _ = error "Aggregation cannot be instantiated by 'realize'"
  realizefrom trace0@(ctx, _) _ = do
    trace ← Trace.subTrace "#aggregation" trace0

Update aggregation

We distinguish an unitialized from an already initialized aggregation. The latter is properly initialized.
We use Welford's online algorithm to update the estimation of mean and variance of the sample statistics. (see https://en.wikipedia.org/wiki/Algorithms_for_calculating_variance#Welford's_Online

```
updateAggregation :: Measurable → Aggregated → LOMeta → Maybe Word64 → Aggregated
updateAggregation v (AggregatedStats s) lme resetAfter =
    let count = fcount (fbasic s)
        reset = maybe False (count ⩾) resetAfter
    in
```

```
    if reset
    then
      singletonStats v
    else
      AggregatedStats $! Stats {flast = v
        ,fold = mkTimestamp
        ,fbasic = updateBaseStats (count >= 1) v (fbasic s)
        ,fdelta = updateBaseStats (count >= 2) (v - flast s) (fdelta s)
        ,ftimed = updateBaseStats (count >= 2) (mkTimestamp - fold s) (ftimed s)
        }
  where
    mkTimestamp = utc2ns (tstamp lme)
    utc2ns (UTCTime days secs) =
      let yearsecs :: Rational
        yearsecs = 365 * 24 * 3600
        rdays, rsecs :: Rational
        rdays = toRational $ toModifiedJulianDay days
        rsecs = toRational secs
        s2ns = 1000000000
      in
      Nanoseconds $ round $ (fromRational $ s2ns * rsecs + rdays * yearsecs :: Double)
updateAggregation v (AggregatedEWMA e) _ _ = AggregatedEWMA $! ewma e v
updateBaseStats :: Bool -> Measurable -> BaseStats -> BaseStats
updateBaseStats False _ s = s {fcount = fcount s + 1}
updateBaseStats True v s =
    let newcount = fcount s + 1
      newvalue = getDouble v
      delta = newvalue - fsum_A s
      dincr = (delta / fromIntegral newcount)
      delta2 = newvalue - fsum_A s - dincr
    in
    BaseStats {fmin = min (fmin s) v
      ,fmax          = max v (fmax s)
      ,fcount = newcount
      ,fsum_A = fsum_A s + dincr
      ,fsum_B = fsum_B s + (delta * delta2)
      }
```

Calculation of EWMA

Following https://en.wikipedia.org/wiki/Moving_average#Exponential_moving_average we calculate the exponential moving average for a series of values Y_t according to:

$$S_t = \begin{cases} Y_1, & t = 1 \\ \alpha \cdot Y_t + (1 - \alpha) \cdot S_{t-1}, & t > 1 \end{cases}$$

The pattern matching below ensures that the EWMA will start with the first value passed in, and

will not change type, once determined.

```
ewma :: EWMA → Measurable → EWMA
ewma (EmptyEWMA a) v = EWMA a v
ewma (EWMA a s@(Microseconds _)) y@(Microseconds _) =
  EWMA a $ Microseconds $ round $ a * (getDouble y) + (1 - a) * (getDouble s)
ewma (EWMA a s@(Seconds _)) y@(Seconds _) =
  EWMA a $ Seconds $ round $ a * (getDouble y) + (1 - a) * (getDouble s)
ewma (EWMA a s@(Bytes _)) y@(Bytes _) =
  EWMA a $ Bytes $ round $ a * (getDouble y) + (1 - a) * (getDouble s)
ewma (EWMA a (PureI s)) (PureI y) =
  EWMA a $ PureI $ round $ a * (fromInteger y) + (1 - a) * (fromInteger s)
ewma (EWMA a (PureD s)) (PureD y) =
  EWMA a $ PureD $ a * y + (1 - a) * s
ewma _ _ = error "Cannot average on values of different type"
```

Chapter 2

Testing

2.1 Test coverage

Test coverage is calculated as the fraction of functions which are called from test routines. This percentage is calculated by the tool *hpc* with a call to

```
cabal new-test
```

Add to a local `cabal.project.local` file these lines:

```
tests:              True
coverage:           True
library-coverage:   True
```

2.2 Test main entry point

```

2.3 Test case generation

2.3.1 instance Arbitrary Aggregated

We define an instance of *Arbitrary* for an `Aggregated` which lets *QuickCheck* generate arbitrary instances of `Aggregated`. For this an arbitrary list of *Integer* is generated and this list is aggregated into a structure of `Aggregated`.

```
instance Arbitrary Aggregated where
  arbitrary = do
    vs' ← arbitrary :: Gen [Integer]
    let vs = 42 : 17 : vs'
      ds = map (λ(a, b) → a − b) $ zip vs (tail vs)
      (m1, s1) = updateMeanVar $ map fromInteger vs
      (m2, s2) = updateMeanVar $ map fromInteger ds
      mkBasicStats = BaseStats
        (PureI (minimum vs))
        (PureI (maximum vs))
        (fromIntegral $ length vs)
        (m1)
        (s1)
      mkDeltaStats = BaseStats
        (PureI (minimum ds))
        (PureI (maximum ds))
        (fromIntegral $ length ds)
        (m2)
        (s2)
      mkTimedStats = BaseStats
        (Nanoseconds 0)
        (Nanoseconds 0)
        (0)
        (0)
        (0)
    return $ AggregatedStats (Stats
      (PureI (last vs))
      (Nanoseconds 0)
      mkBasicStats
      mkDeltaStats
      mkTimedStats)
```

Estimators for mean and variance must be updated the same way as in the code.

```
  updateMeanVar :: [Double] → (Double, Double)
  updateMeanVar [ ] = (0, 0)
  updateMeanVar (val : vals) = updateMeanVar' (val, 0) 1 vals
```

```
  where
    updateMeanVar' (m,s) _ [] = (m,s)
    updateMeanVar' (m,s) cnt (a:r) =
      let delta = a - m
          newcount = cnt + 1
          m' = m + (delta / newcount)
          s' = s + (delta * (a - m'))
      in
      updateMeanVar' (m',s') newcount r
```

Control tracing in a hierarchy of Traces

We can lay out traces in a hierarchical manner, that the children forward traced items to the parent Trace. A NoTrace introduced in this hierarchy will cut off a branch from messaging to the root.

```
unit_hierarchy :: Assertion
unit_hierarchy = do
  msgs ← STM.newTVarIO [ ]
  trace0 ← setupTrace $ TraceConfiguration (TVarList msgs) "test" Neutral Debug
  logInfo trace0 "This should have been displayed!"

  -- subtrace of trace which traces nothing
  setTransformer_ trace0 "inner" (Just NoTrace)

  trace1 ← subTrace "inner" trace0
  logInfo trace1 "This should NOT have been displayed!"

  setTransformer_ trace1 "innermost" (Just Neutral)
  trace2 ← subTrace "innermost" trace1
  logInfo trace2 "This should NOT have been displayed also due to the trace one level above

  -- acquire the traced objects
  res ← STM.readTVarIO msgs

  -- only the first message should have been traced
  assertBool
    ("Found more or less messages than expected: " ++ show res)
    (length res ≡ 1)
```

Change a trace's minimum severity

A trace is configured with a minimum severity and filters out messages that are labelled with a lower severity. This minimum severity of the current trace can be changed.

```
unit_trace_min_severity :: Assertion
unit_trace_min_severity = do
  msgs ← STM.newTVarIO [ ]
  trace@(ctx, _) ← setupTrace $ TraceConfiguration (TVarList msgs) "test min severity" Neutral Debug
  logInfo trace "Message #1"

  -- raise the minimum severity to Warning
  setMinSeverity (configuration ctx) Warning
  msev ← Cardano.BM.Configuration.minSeverity (configuration ctx)
  assertBool ("min severity should be Warning, but is " ++ (show msev))
    (msev ≡ Warning)

  -- this message will not be traced
  logInfo trace "Message #2"

  -- lower the minimum severity to Info
```

```
  setMinSeverity (configuration ctx) Info
  -- this message is traced
  logInfo trace "Message #3"
  -- acquire the traced objects
  res ← STM.readTVarIO msgs
  -- only the first and last messages should have been traced
  assertBool
    ("Found more or less messages than expected: " ++ show res)
    (length res ≡ 2)
  assertBool
    ("Found Info message when Warning was minimum severity: " ++ show res)
    (all (λcase {LogObject _ (LogMessage (LogItem _ Info "Message #2")) → False; _ → True}) res)
```

Define a subtrace's behaviour to duplicate all messages

The `SubTrace` will duplicate all messages that pass through it. Each message will be in its own named context.

```
unit_trace_duplicate :: Assertion
unit_trace_duplicate = do
  msgs ← STM.newTVarIO [ ]
  trace0@(ctx, _) ← setupTrace $ TraceConfiguration (TVarList msgs) "test duplicate" Neutral Debug
