

# Cardano.BM - logging, benchmarking and monitoring

Alexander Diemand

Andreas Triantafyllos

April 2019

### **Abstract**

This is a framework that combines logging, benchmarking and monitoring. Complex evaluations of STM or monadic actions can be observed from outside while reading operating system counters before and after, and calculating their differences, thus relating resource usage to such actions.

Through interactive configuration, the runtime behaviour of logging or the measurement of resource usage can be altered.

Further reduction in logging can be achieved by redirecting log messages to an aggregation function which will output the running statistics with less frequency than the original message.

# Chapter 1

## Logging, benchmarking and monitoring

### 1.1 Main concepts

These are main concepts of the framework:

1. LogObject
2. Trace
3. Backend
4. Configuration

Let's describe each of them.

#### 1.1.1 LogObject

**LogObject** is a message. It contains a logger name, meta information (such as timestamp or severity level) and some particular message:

Please see [Cardano.BM.Data.LogItem](#) for more details.

#### 1.1.2 Trace

You can think of **Trace** as a pipeline for messages. It is a *consumer* of messages from user's point of view and a *source* of messages from framework's point of view.

Please see the section 1.4.1 for more details about ideas behind the **Trace**.

### 1.1.3 Backend

**Backend** is something that can process incoming messages.

The central backend is a **Switchboard**. It sets up other backends and redirects incoming messages to these backends according to configuration:

Please see **Cardano.BM.Data.Backend** and **Cardano.BM.Output.Switchboard** for more details.

### 1.1.4 Configuration

**Configuration** describes how framework parts work together. It can be parsed from the YAML-file or can be defined explicitly as a **Configuration**.

Please note that configuration can be changed at the runtime using interactive editor, see **Cardano.BM.Configuration.Editor** for more details.

## 1.2 Overview

In figure 1.1 we display the relationships among modules in *Cardano.BM*.

### 1.2.1 Backends

As was mentioned earlier, central backend is the **Switchboard** (see `Cardano.BM.Output.Switchboard`) that redirects incoming log messages to selected backends according to **Configuration** (see `Cardano.BM.Configuration.Model`).

The backend **EKGView** (see `Cardano.BM.Output.EKGView`) displays selected values in a browser.

The **Log** backend (see `Cardano.BM.Output.Log`) is based on **katip** package and outputs log items in files or in the console. The format can be chosen to be textual or JSON representation.

The **Aggregation** backend (see `Cardano.BM.Output.Aggregation`) computes simple statistics over incoming log items (e.g. last, min, max, mean, etc.) (see `Cardano.BM.Data.Aggregated` as well).

The **LogBuffer** backend (see `Cardano.BM.Output.LogBuffer`) collects the latest messages from other backends and shows these collected messages via GUI.

Output selection determines which log items of a named context are routed to which backend. In the case of the **Log** output, this includes a configured output sink (e.g. which file). Items that are aggregated lead to the creation of an output of their current statistics. To prevent a potential infinite loop these aggregation statistics cannot be routed again back into the **Aggregation**.

### 1.2.2 Trace

The log items are created in the application's context and passed via a hierarchy of **Traces** (see `Cardano.BM.Trace`). Such a hierarchy can be built with the function `setSubTrace`. The newly added child **Trace** will add its name to the logging context and behave as configured. Among the different kinds of **Traces** implemented are:

1. **NoTrace** which suppresses all log items,
2. **FilterTrace** which filters the log items passing through it,
3. **ObservableTrace** which allows capturing of operating system counters (see `Cardano.BM.Data.SubTrace`).

### 1.2.3 Monitoring

With *Monitoring* we aim to shortcut the logging-analysis cycle and immediately evaluate monitors on logged values when they become available. In case a monitor is triggered a number of actions can be run: either internal actions that can alter the **Configuration**, or actions that can lead to alerting in external systems.

### 1.2.4 IMPORTANT!

It is not the intention that this framework should (as part of normal use) record sufficient information so as to make the sequence of events reproducible, i.e. it is not an audit or transaction log.

Figure 1.1: Overview of module relationships. The arrows indicate import of a module. The arrows with a triangle at one end would signify “inheritance” in object-oriented programming, but we use it to show that one module replaces the other in the namespace, thus specializes its interface.

## 1.3 Requirements

### 1.3.1 Observables

We can observe the passage of the flow of execution through particular points in the code (really the points at which the graph is reduced). Typically observables would be part of an outcome (which has a start and an end). Where the environment permits these outcomes could also gather additional environmental context (e.g read system counters, ‘know’ the time). The proposed framework would be able to aggregate, filter such outcome measures so as to calculation things (where appropriate) such as:

- min/max/mean/variance of the resource costs of achieving an outcome
- elapsed wall-clock time

- CPU cycles
- memory allocations, etc
- exponentially weighted moving average of outcomes, events
- min/max/mean/variance of inter-arrival times of demand for service (the arrival pattern)
- measuring offered load against the system (e.g rate/distribution of requests against the wallet by an exchange, transactions being forwarded between nodes)

### STM evaluation

We treat STM evaluation as a black box and register measurables (counters) before entering, and report the difference at exit together with the result. Logging in an STM will keep a list of log items which at the exit of the evaluation will be passed to the logging subsystem. Since we do not know the exact time an event occurred in the STM action, we annotate the event afterwards with the time interval of the STM action.

### Function evaluation

We treat a function call as a black box and register measurables (counters) before entering, and report the difference at exit together with the result. The function is expected to accept a ‘Trace’ argument which receives the events.

### QuickCheck properties *tentatively*

The function

```
quickCheckResult :: Testable prop => prop -> IO Result
```

will return a *Result* data structure from which we can extract the number of tests performed. Recording the start and end times allows us to derive the time spent for a single test. (although this measurement is wrong as it includes the time spent in QuickCheck setting up the test case (and shrinking?))

## 1.3.2 Traces

Log items are sent as streams of events to the logging system for processing (aggregation, ..) before output. Functions that need to log events must accept a *Trace* argument. There is no monad related to logging in the monad stack, thus this can work in any monadic environment.

### Trace Context

A Trace maintains a named context stack. A new name can be put onto it, and all subsequent log messages are labeled with this named context. This is also true to all downstream functions which receive the modified Trace. We thus can see the call tree and how the evaluation entered the context where a logging function was called. The context also maintains a mapping from name to Severity: this way a logging function call can early end and not produce a log item when the minimum severity is not reached.

## SubTrace

A Trace is created in *IO* within `setupTrace` with the intent to pass the traced items to a downstream logging framework for outputting to various destinations in different formats. Apart from adding a name to the naming stack we can also alter the behaviour of the Trace. The newly created Trace with a specific function to process the recorded items will forward these to the upstream Trace. This way we can, for example, locally turn on aggregation of observables and only report a summary to the logs.

### 1.3.3 Aggregation

Log items contain a named context, severity and a payload (message, structured value). Thinking of a relation

$$(\text{name}, \text{severity}) \rightarrow \text{value}$$

, folding a summarizing function over it outputs

$$(\text{name}, \text{severity}) \rightarrow \text{Summary}$$

. Depending on the type of *value*, the summary could provide for example:

- `*` : first, last, count, the time between events (mean, sigma)
- `Num` : min, max, median, quartiles, mean, sigma, the delta between events (mean, sigma)

Other possible aggregations:

- exponentially weighted moving average
- histograms

### 1.3.4 Monitoring

- Enable (or disable) measuring events and performance at runtime (e.g. measure how block holding time has changed).
- Send alarms when observables give evidence for abnormalities
- Observe actions in progress, i.e. have started and not yet finished
- Bridge to *Datadog*?

### 1.3.5 Reporting

We might want to buffer events in case an exception is detected. This FIFO queue could then be output to the log for post-factum inspection.

### 1.3.6 Visualisation

#### EKG

<https://hackage.haskell.org/package/ekg>

This library allows live monitor a running instance over HTTP. There is a way we can add our own metrics to it and update them.

## Log files

The output of observables immediately or aggregated to log files. The format is chosen to be JSON for easier post-processing.

## Web app

Could combine EKG, log files and parameterization into one GUI.  
(e.g. <https://github.com/HeinrichApfelmus/threepenny-gui>)

# 1.4 Description

## 1.4.1 Contravariant Functors Explanation

**Tracer**'s implementations is based on a **contravariant** package.

Please see the presentation in docs/pres-20190409/contravariant-idea to understand the core idea of the contravariant functor.

## 1.4.2 Logging with **Trace**

### Setup procedure

Figure 1.2: Setup procedure

## Hierarchy of **Traces**

### 1.4.3 Micro-benchmarks record observables

Micro-benchmarks are recording observables that measure resource usage of the whole program for a specific time. These measurements are then associated with the subsystem that was observed at that time. Caveat: if the executable under observation runs on a multiprocessor computer where more than one parallel thread executes at the same time, it becomes difficult to associate resource usage to a single function. Even more so, as Haskell's thread do not map directly to operating system threads. So the expressiveness of our approach is only valid statistically when a large number of observables have been captured.

## Counters

The framework provides access to the following O/S counters (defined in **ObservableInstance**) on *Linux*:

- monotonic clock (see **MonotonicClock**)
- CPU or total time (`/proc/<pid>/stat`) (see **ProcessStats**)
- memory allocation (`/proc/<pid>/statm`) (see **MemoryStats**)
- network bytes received/sent (`/proc/<pid>/net/netstat`) (see **NetStats**)
- disk input/output (`/proc/<pid>/io`) (see **IOStats**)

On all platforms, access is provided to the *RTS* counters (see **GhcRtsStats**).

## Implementing micro-benchmarks

In a micro-benchmark we capture operating system counters over an STM evaluation or a function, before and afterwards. Then, we compute the difference between the two and report all three measurements via a *Trace* to the logging system. Here we refer to the example that can be found in **complex example**.

The capturing of STM actions is defined in **Cardano.BM.Observer.STM** and the function `STM.bracketObserveIO` has type:

```
STM.bracketObserveIO trace "observeSTM" (stmAction args)
```

```
bracketObserveIO :: Trace IO -> Text -> STM.STM t -> IO t
```

It accepts a *Trace* to which it logs, adds

a name to the context name and enters this with a *SubTrace*, and finally the STM action which will be evaluated. Because this evaluation can be retried, we cannot pass to it a *Trace* to which it could log directly. A variant of this function **bracketObserveLogIO** also captures log items in its result, which then are threaded through the *Trace*.

Capturing observables for a function evaluation in *IO*, the type of `bracketObserveIO` (defined in **Cardano.BM.Observer.Monad**) is:

```
bracketObserveIO :: Trace IO -> Text -> IO t -> IO t
```

It accepts a *Trace* to which it logs items, adds a name to the context name and enters this with a *SubTrace*, and then the IO action which will be evaluated.

Counters are evaluated before the evaluation and afterwards. We trace these as log items **ObserveOpen** and **ObserveClose**, as well as the difference with type **ObserveDiff**.

```
bracketObserveIO trace "observeDownload" $ do
  license <- openURI "http://www.gnu.org/licenses/gpl.txt"
  case license of
    Right bs -> logInfo trace $ pack $ BS8.unpack bs
    Left e    -> logError trace $ "failed to download; error: " ++ (show e)
  threadDelay 50000 -- .05 second
  pure ()
```

### Configuration of mu-benchmarks

Observed STM actions or functions enter a new named context with a SubTrace. Thus, they need a configuration of the behaviour of this SubTrace in the new context. We can define this in the configuration for our example:

```
CM.setSubTrace c "complex.observeDownload" (Just $ ObservableTrace [NetStats,IOStats])
```

This enables the capturing of network and I/O stats from the operating system. Other Observables are implemented in [Cardano.BM.Data.Observable](#). Captured observables need to be routed to backends. In our example we configure:

```
CM.setBackends c "complex.observeIO" (Just [AggregationBK])
```

to direct observables from named context *complex.observeIO* to the Aggregation backend.

#### 1.4.4 Configuration

##### Format

The configuration is parsed from a file in *Yaml* format (see <https://en.wikipedia.org/wiki/YAML>) on startup. In a first parsing step the file is loaded into an internal *Representation*. This structure is then further processed and validated before copied into the runtime [Configuration](#).

##### Configuration editor

The configuration editor (figure [1.3](#)) provides a minimalistic GUI accessible through a browser that directly modifies the runtime configuration of the logging system. Most importantly, the global minimum severity filter can be set. This will suppress all log messages that have a severity assigned that is lower than this setting. Moreover, the following behaviours of the logging system can be changed through the GUI:

- *Backends*: relates the named logging context to a [BackendKind](#)
- *Scribes*: if the backend is *KatipBK*, defines to which outputs the messages are directed (see [ScribeId](#))
- *Severities* a local minimum severity filter for just the named context (see [Severity](#))
- *SubTrace* entering a new named context can create a new [Trace](#) with a specific behaviour (see [SubTrace](#))
- *Aggregation* if the backend is *AggregationBK*, defines which aggregation method to use (see [AggregatedKind](#))

Figure 1.3: The configuration editor is listening on *localhost* and can be accessed through a browser. At the top is the setting for the global minimum severity filter, that drops all messages that have a severity lower than this setting. Below are the settings for various behaviours of the logging system.

### 1.4.5 Information reduction in **Aggregation**

#### Statistics

## 1.5 Examples

### 1.5.1 Simple example showing plain logging

```
{-# LANGUAGE ScopedTypeVariables #-}
module Main
  (main)
  where
import Control.Concurrent (threadDelay)
import Cardano.BM.Configuration.Static (defaultConfigStdout)
import Cardano.BM.Setup (setupTrace)
import Cardano.BM.Trace (Trace, logDebug, logError, logInfo,
```

```

        logNotice, logWarning)
main :: IO ()
main = do
    c ← defaultConfigStdout
    tr :: Trace IO String ← setupTrace (Right c) "simple"
    logDebug tr "this is a debug message"
    logInfo tr "this is an information."
    logNotice tr "this is a notice!"
    logWarning tr "this is a warning!"
    logError tr "this is an error!"
    threadDelay 80000
    return ()

```

## 1.5.2 Complex example showing logging, aggregation, and observing IO actions

### Module header and import directives

```

{-# LANGUAGE CPP #-}

  return ()

```

## 1.6 Code listings - contra-tracer package

### 1.6.1 Examples

Tracing using the contravariant **Tracer** naturally reads:

```

let logTrace = traceWith $ showTracing $ stdoutTracer
in logTrace "hello world"

```

### 1.6.2 Contravariant **Tracer**

The notion of a **Tracer** is an action that can be used to observe information of interest during evaluation. **Tracers** can capture (and annotate) such observations with additional information from their execution context.

```

newtype Tracer m a = Tracer {runTracer :: a → m ()}

```

A **Tracer** is an instance of *Contravariant*, which permits new **Tracers** to be constructed that feed into the existing Tracer by use of *contramap*.

```

instance Contravariant (Tracer m) where
  contramap f (Tracer t) = Tracer (t ∘ f)

```

Although a **Tracer** is invoked in a monadic context (which may be *Identity*), the construction of a new **Tracer** is a pure function. This brings with it the constraint that the derived **Tracers** form a hierarchy which has its root at the top level tracer.

In principle a **Tracer** is an instance of *Semigroup* and *Monoid*, by sequential composition of the tracing actions.

```
instance Applicative m => Semigroup (Tracer m s) where
  Tracer a1 <> Tracer a2 = Tracer $ \s -> a1 s * > a2 s
instance Applicative m => Monoid (Tracer m s) where
  mappend = (<>)
  mempty = nullTracer
```

### nullTracer

The simplest tracer - one that suppresses all output.

```
nullTracer :: Applicative m => Tracer m a
nullTracer = Tracer $ \_ -> pure ()
```

### traceWith

```
traceWith :: Tracer m a -> a -> m ()
traceWith = runTracer
```

## 1.6.3 Transformers

### Applying *show* on a **Tracer**'s messages

The Tracer transformer exploiting Show.

```
showTracing :: (Show a) => Tracer m String -> Tracer m a
showTracing = contramap show
```

### Conditional tracing - statically defined

The Tracer transformer that allows for on/off control of tracing at trace creation time.

```
condTracing :: (Monad m) => (a -> Bool) -> Tracer m a -> Tracer m a
condTracing active tr = Tracer $ \s ->
  when (active s) (traceWith tr s)
```

### Conditional tracing - dynamically evaluated

The tracer transformer that can exercise dynamic control over tracing, the dynamic decision being made using the context accessible in the monadic context.

```
condTracingM :: (Monad m) => m (a -> Bool) -> Tracer m a -> Tracer m a
condTracingM activeP tr = Tracer $ \s -> do
  active <- activeP
  when (active s) (traceWith tr s)
```

**natTrace**

Natural transformation from monad  $m$  to monad  $n$ .

```
natTracer :: (forall x ◦ m x → n x) → Tracer m s → Tracer n s
natTracer nat (Tracer tr) = Tracer (nat ◦ tr)
```

**1.6.4 Output****Directing a Tracer's output to stdout**

The Tracer that prints a string (as a line) to stdout (usual caveats about interleaving should be heeded).

```
stdoutTracer :: (MonadIO m) ⇒ Tracer m String
stdoutTracer = Tracer $ liftIO ◦ putStrLn
```

**Outputting a Tracer with Debug.Trace**

A Tracer that uses *TraceM* (from **Debug.Trace**) as its output mechanism.

```
debugTracer :: (Applicative m) ⇒ Tracer m String
debugTracer = Tracer Debug.Trace.traceM
```

**1.7 Code listings - iohk-monitoring package****1.7.1 Cardano.BM.Observer.STM**

```
stmWithLog :: STM.STM (t, [(LOMeta, LOContent a)]) → STM.STM (t, [(LOMeta, LOContent a)])
stmWithLog action = action
```

**Observe STM action in a named context**

With given name, create a **SubTrace** according to **Configuration** and run the passed STM action on it.

```
bracketObserveIO :: Config.Configuration → Trace IO a → Severity → Text → STM.STM t → IO t
bracketObserveIO config trace severity name action = do
  subTrace ← fromMaybe Neutral < $ > Config.findSubTrace config name
  bracketObserveIO' subTrace severity trace action
where
  bracketObserveIO' :: SubTrace → Severity → Trace IO a → STM.STM t → IO t
  bracketObserveIO' NoTrace _ _ act =
    STM.atomically act
  bracketObserveIO' subtrace sev logTrace act = do
    mCountersid ← observeOpen subtrace sev logTrace
    -- run action; if an exception is caught, then it will be logged and rethrown.
    t ← (STM.atomically act) 'catch' (λ(e :: SomeException) → (TIO.hPutStrLn stderr (pack (show e)) >> throw e))
    case mCountersid of
      Left openException →
```

```

-- since observeOpen faced an exception there is no reason to call observeClose
-- however the result of the action is returned
TIO.hPutStrLn stderr ("ObserveOpen: " <> pack (show openException))
Right countersid → do
  res ← observeClose subtrace sev logTrace countersid [ ]
  case res of
    Left ex → TIO.hPutStrLn stderr ("ObserveClose: " <> pack (show ex))
    _ → pure ()
pure t

```

### Observe STM action in a named context and output captured log items

The STM action might output messages, which after "success" will be forwarded to the logging trace. Otherwise, this function behaves the same as **bracketObserveIO**.

```

bracketObserveLogIO :: Config.Configuration → Trace IO a → Severity → Text → STM.STM (t, [(LOMeta, LOContent a)])
bracketObserveLogIO config trace severity name action = do
  subTrace ← fromMaybe Neutral < $ > Config.findSubTrace config name
  bracketObserveLogIO' subTrace severity trace action
where
  bracketObserveLogIO' :: SubTrace → Severity → Trace IO a → STM.STM (t, [(LOMeta, LOContent a)])
  bracketObserveLogIO' NoTrace _ _ act = do
    (t, _) ← STM.atomically $ stmWithLog act
    pure t
  bracketObserveLogIO' subtrace sev logTrace act = do
    mCountersid ← observeOpen subtrace sev logTrace
    -- run action, return result and log items; if an exception is
    -- caught, then it will be logged and rethrown.
    (t, as) ← (STM.atomically $ stmWithLog act) 'catch'
    (λ(e :: SomeException) → (TIO.hPutStrLn stderr (pack (show e)) >> throwM e))
  case mCountersid of
    Left openException →
      -- since observeOpen faced an exception there is no reason to call observeClose
      -- however the result of the action is returned
      TIO.hPutStrLn stderr ("ObserveOpen: " <> pack (show openException))
    Right countersid → do
      res ← observeClose subtrace sev logTrace countersid as
      case res of
        Left ex → TIO.hPutStrLn stderr ("ObserveClose: " <> pack (show ex))
        _ → pure ()
    pure t

```

## 1.7.2 Cardano.BM.Observer.Monad

### Monad.bracketObserverIO

Observes an IO action and adds a name to the logger name of the passed in **Trace**. An empty **Text** leaves the logger name untouched.

Microbenchmarking steps:

1. Create a *trace* which will have been configured to observe things besides logging.

```
import qualified Cardano.BM.Configuration.Model as CM
○○○
c ← config
trace ← setupTrace (Right c) "demo-playground"
where
  config :: IO CM.Configuration
  config = do
    c ← CM.empty
    CM.setMinSeverity c Debug
    CM.setSetupBackends c [KatipBK, AggregationBK]
    CM.setDefaultBackends c [KatipBK, AggregationBK]
    CM.setSetupScribes c [ScribeDefinition {
      scName = "stdout"
    , scKind = StdoutSK
    , scRotation = Nothing
    }
    ]
    CM.setDefaultScribes c ["StdoutSK::stdout"]
  return c
```

2. *c* is the **Configuration** of *trace*. In order to enable the collection and processing of measurements (min, max, mean, std-dev) *AggregationBK* is needed.

```
CM.setDefaultBackends c [KatipBK, AggregationBK]
```

in a configuration file (YAML) means

```
defaultBackends:
  - KatipBK
  - AggregationBK
```

3. Set the measurements that you want to take by changing the configuration of the *trace* using **setSubTrace**, in order to declare the namespace where we want to enable the particular measurements and the list with the kind of measurements.

```
CM.setSubTrace
  config
  "demo-playground.submit-tx"
  (Just $ ObservableTrace observablesSet)
where
  observablesSet = [MonotonicClock, MemoryStats]
```

4. Find an action to measure. e.g.:

```
runProtocolWithPipe x hdl proto 'catch' (λProtocolStopped → return ())
```

and use **bracketObserveIO**. e.g.:

```
bracketObserveIO trace "submit-tx" $
  runProtocolWithPipe x hdl proto 'catch' (λProtocolStopped → return ())
```

```
bracketObserveIO :: Config.Configuration → Trace IO a → Severity → Text → IO t → IO t
bracketObserveIO config trace severity name action = do
```

```

subTrace ← fromMaybe Neutral < $ > Config.findSubTrace config name
bracketObserveIO' subTrace severity trace action
where
bracketObserveIO' :: SubTrace → Severity → Trace IO a → IO t → IO t
bracketObserveIO' NoTrace _ _ act = act
bracketObserveIO' subtrace sev logTrace act = do
  mCountersid ← observeOpen subtrace sev logTrace
  -- run action; if an exception is caught it will be logged and rethrown.
  t ← act 'catch' (λ(e :: SomeException) → (TIO.hPutStrLn stderr (pack (show e)) >> throwM e))
  case mCountersid of
    Left openException →
      -- since observeOpen faced an exception there is no reason to call observeClose
      -- however the result of the action is returned
      TIO.hPutStrLn stderr ("ObserveOpen: " <> pack (show openException))
    Right countersid → do
      res ← observeClose subtrace sev logTrace countersid [ ]
      case res of
        Left ex → TIO.hPutStrLn stderr ("ObserveClose: " <> pack (show ex))
        _ → pure ()
  pure t

```

### Monadic.bracketObserverM

Observes a *MonadIO*  $m \Rightarrow m$  action and adds a name to the logger name of the passed in **Trace**.  
An empty *Text* leaves the logger name untouched.

```

bracketObserveM :: (MonadCatch m, MonadIO m) => Config.Configuration → Trace IO a → Severity → Text → m t
bracketObserveM config trace severity name action = do
  subTrace ← liftIO $ fromMaybe Neutral < $ > Config.findSubTrace config name
  bracketObserveM' subTrace severity trace action
where
bracketObserveM' :: (MonadCatch m, MonadIO m) => SubTrace → Severity → Trace IO a → m t → m t
bracketObserveM' NoTrace _ _ act = act
bracketObserveM' subtrace sev logTrace act = do
  mCountersid ← liftIO $ observeOpen subtrace sev logTrace
  -- run action; if an exception is caught it will be logged and rethrown.
  t ← act 'catch' (λ(e :: SomeException) → liftIO (TIO.hPutStrLn stderr (pack (show e)) >> throwM e))
  case mCountersid of
    Left openException →
      -- since observeOpen faced an exception there is no reason to call observeClose
      -- however the result of the action is returned
      liftIO $ TIO.hPutStrLn stderr ("ObserveOpen: " <> pack (show openException))
    Right countersid → do
      res ← liftIO $ observeClose subtrace sev logTrace countersid [ ]
      case res of
        Left ex → liftIO (TIO.hPutStrLn stderr ("ObserveClose: " <> pack (show ex)))
        _ → pure ()
  pure t

```

**observerOpen**

```

observeOpen :: SubTrace → Severity → Trace IO a → IO (Either SomeException CounterState)
observeOpen subtrace severity logTrace = (do
  identifier ← newUnique
  -- take measurement
  counters ← readCounters subtrace
  let state = CounterState identifier counters
  if counters ≡ []
  then return ()
  else do
    -- send opening message to Trace
    traceNamedObject logTrace ≪
      (,) < $ > (mkLOMeta severity Confidential) < * > pure (ObserveOpen state)
  return (Right state)) 'catch' (return ∘ Left)

```

**observeClose**

```

observeClose
  :: SubTrace
  → Severity
  → Trace IO a
  → CounterState
  → [(LOMeta, LOContent a)]
  → IO (Either SomeException ())
observeClose subtrace sev logTrace initState logObjects = (do
  let identifier = csIdentifier initState
      initialCounters = csCounters initState
  -- take measurement
  counters ← readCounters subtrace
  if counters ≡ []
  then return ()
  else do
    mle ← mkLOMeta sev Confidential
    -- send closing message to Trace
    traceNamedObject logTrace $
      (mle, ObserveClose (CounterState identifier counters))
    -- send diff message to Trace
    traceNamedObject logTrace $
      (mle, ObserveDiff (CounterState identifier (diffCounters initialCounters counters)))
    -- trace the messages gathered from inside the action
    forM_ logObjects $ traceNamedObject logTrace
    return (Right ())) 'catch' (return ∘ Left)

```

**1.7.3 Cardano.BM.Trace****Utilities**

Natural transformation from monad  $m$  to monad  $n$ .

```

natTrace :: (forall x o m x → n x) → Trace m a → Trace n a
natTrace nat basetrace = natTracer nat basetrace

```

### Enter new named context

A new context name is added.

```

appendName :: MonadIO m ⇒ LoggerName → Trace m a → m (Trace m a)
appendName name =
  modifyName (λprevLoggerName → appendWithDot name prevLoggerName)
appendWithDot :: LoggerName → LoggerName → LoggerName
appendWithDot " " newName = newName
appendWithDot xs " " = xs
appendWithDot xs newName = xs <> " ." <> newName

```

### Change named context

The context name is overwritten.

```

modifyName :: MonadIO m ⇒ (LoggerName → LoggerName) → Trace m a → m (Trace m a)
modifyName f basetrace = return $ modifyNameBase f basetrace
modifyNameBase
  :: (LoggerName → LoggerName)
  → Tracer m (LogObject a)
  → Tracer m (LogObject a)
modifyNameBase k = contramap f
where
  f (LogObject name meta item) = LogObject (k name) meta item

```

### Contramap a trace and produce the naming context

```

named :: Tracer m (LogObject a) → Tracer m (LOMeta, LOContent a)
named = contramap $ uncurry (LogObject mempty)

```

### Trace a **LogObject** through

```

traceNamedObject
  :: MonadIO m
  ⇒ Trace m a
  → (LOMeta, LOContent a)
  → m ()
traceNamedObject logTrace lo =
  traceWith (named logTrace) lo

```

### Evaluation of **FilterTrace**

A filter consists of a *DropName* and a list of *UnhideNames*. If the context name matches the *DropName* filter, then at least one of the *UnhideNames* must match the name to have the evaluation of the filters return *True*.

```
evalFilters :: [(DropName, UnhideNames)] → LoggerName → Bool
evalFilters fs nm =
  all (λ(no, yes) → if (dropFilter nm no) then (unhideFilter nm yes) else True) fs
where
  dropFilter :: LoggerName → DropName → Bool
  dropFilter name (Drop sel) = {-not -} (matchName name sel)
  unhideFilter :: LoggerName → UnhideNames → Bool
  unhideFilter _ (Unhide []) = False
  unhideFilter name (Unhide us) = any (λsel → matchName name sel) us
  matchName :: LoggerName → NameSelector → Bool
  matchName name (Exact name') = name == name'
  matchName name (StartsWith prefix) = T.isPrefixOf prefix name
  matchName name (EndsWith postfix) = T.isSuffixOf postfix name
  matchName name (Contains name') = T.isInfixOf name' name
```

### Concrete Trace on stdout

This function returns a trace with an action of type "**LogObject** *a* → IO ()" which will output a text message as text and all others as JSON encoded representation to the console.

TODO remove *locallock*

```
locallock :: MVar ()
locallock = unsafePerformIO $ newMVar ()

stdoutTrace :: Tracer IO (LogObject T.Text)
stdoutTrace = Tracer $ λ(LogObject logname _ lc) →
  withMVar locallock $ \_ →
    case lc of
      (LogMessage logItem) →
        output logname $ logItem
      obj →
        output logname $ toStrict (encodeToLazyText obj)
where
  output nm msg = TIO.putStrLn $ nm <> " :: " <> msg
```

### Concrete Trace into a TVar

```
traceInTVar :: STM.TVar [a] → Tracer STM.STM a
traceInTVar tvar = Tracer $ λa → STM.modifyTVar tvar ((:) a)

traceInTVarIO :: STM.TVar [a] → Tracer IO a
traceInTVarIO tvar = Tracer $ λa →
  STM.atomically $ STM.modifyTVar tvar ((:) a)
```

**Enter message into a trace**

The function `traceNamedItem` creates a `LogObject` and threads this through the action defined in the `Trace`.

```

traceNamedItem
  :: MonadIO m
  ⇒ Trace m a
  → PrivacyAnnotation
  → Severity
  → a
  → m ()
traceNamedItem logTrace p s m =
  traceNamedObject logTrace ≪
    (,) < $ > liftIO (mkLOMeta s p)
    < * > pure (LogMessage m)

```

**Logging functions**

```

logDebug, logInfo, logNotice, logWarning, logError, logCritical, logAlert, logEmergency
  :: MonadIO m ⇒ Trace m a → a → m ()
logDebug logTrace = traceNamedItem logTrace Public Debug
logInfo logTrace = traceNamedItem logTrace Public Info
logNotice logTrace = traceNamedItem logTrace Public Notice
logWarning logTrace = traceNamedItem logTrace Public Warning
logError logTrace = traceNamedItem logTrace Public Error
logCritical logTrace = traceNamedItem logTrace Public Critical
logAlert logTrace = traceNamedItem logTrace Public Alert
logEmergency logTrace = traceNamedItem logTrace Public Emergency
logDebugS, logInfoS, logNoticeS, logWarningS, logErrorS, logCriticalS, logAlertS, logEmergencyS
  :: MonadIO m ⇒ Trace m a → a → m ()
logDebugS logTrace = traceNamedItem logTrace Confidential Debug
logInfoS logTrace = traceNamedItem logTrace Confidential Info
logNoticeS logTrace = traceNamedItem logTrace Confidential Notice
logWarningS logTrace = traceNamedItem logTrace Confidential Warning
logErrorS logTrace = traceNamedItem logTrace Confidential Error
logCriticalS logTrace = traceNamedItem logTrace Confidential Critical
logAlertS logTrace = traceNamedItem logTrace Confidential Alert
logEmergencyS logTrace = traceNamedItem logTrace Confidential Emergency

```

**1.7.4 Cardano.BM.Setup****setupTrace**

Setup a new `Trace` with either a given `Configuration` or a `FilePath` to a configuration file. After all tracing operations have ended; `shutdownTrace` must be called.

```

setupTrace :: (MonadIO m, ToObject a) ⇒ Either FilePath Config.Configuration → Text → m (Trace m a)
setupTrace (Left cfgFile) name = do
  c ← liftIO $ Config.setup cfgFile
  fst < $ > setupTrace_ c name

```

Figure 1.4: Setup procedure

```

setupTrace (Right c) name = fst < $ > setupTrace_c name
setupTrace_ :: (MonadIO m, ToObject a) => Config.Configuration -> Text -> m (Trace m a, Switchboard.Switchboard a)
setupTrace_c name = do
  sb <- liftIO $ Switchboard.realize c
  tr <- appendName name $ natTrace liftIO (Switchboard.mainTraceConditionally c sb)
  return (tr, sb)
  
```

### shutdown

Shut down the Switchboard and all the **Traces** related to it.

```

shutdown :: ToObject a => Switchboard.Switchboard a -> IO ()
shutdown = Switchboard.unrealize
  
```

### withTrace

Setup a **Trace** from **Configuration** and pass it to the action. At the end, shutdown all the components and close the trace.

```

withTrace :: (MonadIO m, MonadMask m, ToObject a) => Config.Configuration -> Text -> (Trace m a -> m t)
withTrace cfg name action =
  bracket
    (setupTrace_cfg name)           -- acquire
    (\(_, sb) -> liftIO $ shutdown sb) -- release
    (\(tr, _) -> action tr)         -- action
  
```

### 1.7.5 Cardano.BM.Counters

Here the platform is chosen on which we compile this program.

Currently, we mainly support *Linux* with its 'proc' filesystem.

```

{-# LANGUAGE CPP #-}
# if defined (linux_HOST_OS)
# define LINUX
  
```

```

# endif
module Cardano.BM.Counters
(
    Platform.readCounters
    , diffTimeObserved
    , getMonoClock
) where
# ifdef LINUX
import qualified Cardano.BM.Counters.Linux as Platform
# else
import qualified Cardano.BM.Counters.Dummy as Platform
# endif
import Cardano.BM.Counters.Common (getMonoClock)
import Cardano.BM.Data.Aggregated (Measurable (..))
import Cardano.BM.Data.Counter

```

### Calculate difference between clocks

```

diffTimeObserved :: CounterState → CounterState → Measurable
diffTimeObserved (CounterState id0 startCounters) (CounterState id1 endCounters) =
    let
        startTime = getMonotonicTime startCounters
        endTime = getMonotonicTime endCounters
    in
    if (id0 == id1)
    then endTime - startTime
    else error "these clocks are not from the same experiment"
where
    getMonotonicTime counters = case (filter isMonotonicClockCounter counters) of
        [(Counter MonotonicClockTime _ mus)] → mus
        _ → error "A time measurement is missing!"
    isMonotonicClockCounter :: Counter → Bool
    isMonotonicClockCounter = (MonotonicClockTime ==) ∘ cType

```

#### 1.7.6 Cardano.BM.Counters.Common

Common functions that serve *readCounters* on all platforms.

```

nominalTimeToMicroseconds :: Word64 → Microsecond
nominalTimeToMicroseconds = fromMicroseconds ∘ toInteger ∘ ('div' 1000)

```

### Read monotonic clock

```

getMonoClock :: IO [Counter]
getMonoClock = do
    t ← getMonotonicTimeNSec
    return [Counter MonotonicClockTime "monoclock" $ Microseconds (t `div' 1000)]

```

### Read GHC RTS statistics

Read counters from GHC's *RTS* (runtime system). The values returned are as per the last GC (garbage collection) run.

```

readRTSStats :: IO [Counter]
readRTSStats = do
    iscollected ← GhcStats.getRTSStatsEnabled
    if iscollected
    then ghcstats
    else return []
where
    ghcstats :: IO [Counter]
    ghcstats = do
        -- need to run GC?
        rts ← GhcStats.getRTSStats
        let getrts = ghcval rts
        return [getrts (Bytes ∘ fromIntegral ∘ GhcStats.allocated_bytes, "bytesAllocated")
            ,getrts (Bytes ∘ fromIntegral ∘ GhcStats.max_live_bytes, "liveBytes")
            ,getrts (Bytes ∘ fromIntegral ∘ GhcStats.max_large_objects_bytes, "largeBytes")
            ,getrts (Bytes ∘ fromIntegral ∘ GhcStats.max_compact_bytes, "compactBytes")
            ,getrts (Bytes ∘ fromIntegral ∘ GhcStats.max_slop_bytes, "slopBytes")
            ,getrts (Bytes ∘ fromIntegral ∘ GhcStats.max_mem_in_use_bytes, "usedMemBytes")
            ,getrts (Nanoseconds ∘ fromIntegral ∘ GhcStats.gc_cpu_ns, "gcCpuNs")
            ,getrts (Nanoseconds ∘ fromIntegral ∘ GhcStats.gc_elapsed_ns, "gcElapsedNs")
            ,getrts (Nanoseconds ∘ fromIntegral ∘ GhcStats.cpu_ns, "cpuNs")
            ,getrts (Nanoseconds ∘ fromIntegral ∘ GhcStats.elapsed_ns, "elapsedNs")
            ,getrts (PureI ∘ toInteger ∘ GhcStats.gcs, "gcNum")
            ,getrts (PureI ∘ toInteger ∘ GhcStats.major_gcs, "gcMajorNum")
            ]
    ghcval :: GhcStats.RTSStats → ((GhcStats.RTSStats → Measurable), Text) → Counter
    ghcval s (f, n) = Counter RTSStats n $ (f s)

```

### 1.7.7 Cardano.BM.Counters.Dummy

This is a dummy definition of *readCounters* on platforms that do not support the 'proc' filesystem from which we would read the counters.

The only supported measurements are monotonic clock time and RTS statistics for now.

```

readCounters :: SubTrace → IO [Counter]
readCounters NoTrace      = return []
readCounters Neutral      = return []
readCounters (TeeTrace _) = return []
readCounters (FilterTrace _) = return []
readCounters UntimedTrace = return []
readCounters DropOpening  = return []
# ifdef ENABLE_OBSERVABLES
readCounters (ObservableTrace tts) = foldrM (λ(sel, fun) a →
    if any (≡ sel) tts
    then (fun >>= λxs → return $ a ++ xs)
    else return a) [] selectors
where

```

```

        selectors = [(MonotonicClock, getMonoClock)
                     , (GhcRtsStats, readRTSStats)
                     ]
# else
readCounters (ObservableTrace _) = return []
# endif

```

### 1.7.8 Cardano.BM.Counters.Linux

we have to expand the `readMemStats` function  
to read full data from `proc`

```

readCounters :: SubTrace → IO [Counter]
readCounters NoTrace      = return []
readCounters Neutral      = return []
readCounters TeeTrace _   = return []
readCounters FilterTrace _ = return []
readCounters UntimedTrace = return []
readCounters DropOpening  = return []
# ifdef ENABLE_OBSERVABLES
readCounters (ObservableTrace tts) = do
    pid ← getProcessID
    foldrM (λ(sel, fun) a →
        if any (≡ sel) tts
        then (fun >>= λxs → return $ a ++ xs)
        else return a) [] (selectors pid)
    where
        selectors pid = [(MonotonicClock, getMonoClock)
                        , (MemoryStats, readProcStatM pid)
                        , (ProcessStats, readProcStats pid)
                        , (NetStats, readProcNet pid)
                        , (IOStats, readProcIO pid)
                        , (GhcRtsStats, readRTSStats)
                        ]
# else
readCounters (ObservableTrace _) = return []
# endif

# ifdef ENABLE_OBSERVABLES
pathProc :: FilePath
pathProc = "/proc/"
pathProcStat :: ProcessID → FilePath
pathProcStat pid = pathProc </> (show pid) </> "stat"
pathProcStatM :: ProcessID → FilePath
pathProcStatM pid = pathProc </> (show pid) </> "statm"
pathProcIO :: ProcessID → FilePath
pathProcIO pid = pathProc </> (show pid) </> "io"
pathProcNet :: ProcessID → FilePath
pathProcNet pid = pathProc </> (show pid) </> "net" </> "netstat"
# endif

```

**Reading from a file in /proc/<pid >**

```
# ifdef ENABLE_OBSERVABLES
readProcList :: FilePath → IO [Integer]
readProcList fp = do
    cs ← readFile fp
    return $ map (\s → maybe 0 id $ (readMaybe s :: Maybe Integer)) (words cs)
# endif
```

**readProcStatM - /proc/<pid >/statm**

```
/proc/[pid]/statm
Provides information about memory usage, measured in pages. The columns are:
    size      (1) total program size
                (same as VmSize in /proc/[pid]/status)
    resident   (2) resident set size
                (same as VmRSS in /proc/[pid]/status)
    shared     (3) number of resident shared pages (i.e., backed by a file)
                (same as RssFile+RssShmem in /proc/[pid]/status)
    text       (4) text (code)
    lib        (5) library (unused since Linux 2.6; always 0)
    data       (6) data + stack
    dt         (7) dirty pages (unused since Linux 2.6; always 0)
```

```
# ifdef ENABLE_OBSERVABLES
readProcStatM :: ProcessID → IO [Counter]
readProcStatM pid = do
    ps0 ← readProcList (pathProcStatM pid)
    let ps = zip colnames ps0
        psUseful = filter (("unused" ≠) ∘ fst) ps
    return $ map (\(n,i) → Counter MemoryCounter n (PureI i)) psUseful
where
    colnames :: [Text]
    colnames = ["size", "resident", "shared", "text", "unused", "data", "unused"]
# endif
```

**readProcStats - //proc//<pid >//stat**

```
/proc/[pid]/stat
Status information about the process. This is used by ps(1). It is defined in the kernel source file
fs/proc/array.c.
```

The fields, in order, with their proper scanf(3) format specifiers, are listed below. Whether or not certain of these fields display valid information is governed by a ptrace access mode PTRACE\_MODE\_READ\_FSCREDS | PTRACE\_MODE\_NOAUDIT check (refer to ptrace(2)). If the check denies access, then the field value is displayed as 0. The affected fields are indicated with the marking [PT].

- (1) pid %d  
The process ID.
- (2) comm %s  
The filename of the executable, in parentheses. This is visible whether or not the executable is swapped out.
- (3) state %c  
One of the following characters, indicating process state:  
  
R Running  
  
S Sleeping in an interruptible wait

D Waiting in uninterruptible disk sleep  
 Z Zombie  
 T Stopped (on a signal) or (before Linux 2.6.33) trace stopped  
 t Tracing stop (Linux 2.6.33 onward)  
 W Paging (only before Linux 2.6.0)  
 X Dead (from Linux 2.6.0 onward)  
 x Dead (Linux 2.6.33 to 3.13 only)  
 K Wakekill (Linux 2.6.33 to 3.13 only)  
 W Waking (Linux 2.6.33 to 3.13 only)  
 P Parked (Linux 3.9 to 3.13 only)

(4) ppid %d  
 The PID of the parent of this process.

(5) pgrp %d  
 The process group ID of the process.

(6) session %d  
 The session ID of the process.

(7) tty\_nr %d  
 The controlling terminal of the process. (The minor device number is contained in the combination of bits 31 to 20 and 7 to 0; the major device number is in bits 15 to 8.)

(8) tpgid %d  
 The ID of the foreground process group of the controlling terminal of the process.

(9) flags %u  
 The kernel flags word of the process. For bit meanings, see the PF\_\* defines in the Linux kernel source file include/linux/sched.h. Details depend on the kernel version.  
  
 The format for this field was %lu before Linux 2.6.

(10) minflt %lu  
 The number of minor faults the process has made which have not required loading a memory page from disk.

(11) cminflt %lu  
 The number of minor faults that the process's waited-for children have made.

(12) majflt %lu  
 The number of major faults the process has made which have required loading a memory page from disk.

(13) cmajflt %lu  
 The number of major faults that the process's waited-for children have made.

(14) utime %lu  
 Amount of time that this process has been scheduled in user mode, measured in clock ticks (divide by sysconf(\_SC\_CLK\_TCK)). This includes guest time, guest\_time (time spent running a virtual CPU, see below), so that applications that are not aware of the guest time field do not lose that time from their calculations.

(15) stime %lu  
 Amount of time that this process has been scheduled in kernel mode, measured in clock ticks (divide by sysconf(\_SC\_CLK\_TCK)).

(16) cutime %ld  
 Amount of time that this process's waited-for children have been scheduled in user mode, measured in clock ticks (divide by sysconf(\_SC\_CLK\_TCK)). (See also times(2).) This includes guest time, cguest\_time (time spent running a virtual CPU, see below).

(17) cstime %ld

Amount of time that this process's waited-for children have been scheduled in kernel mode, measured in clock ticks (divide by `sysconf(_SC_CLK_TCK)`).

- (18) `priority` %ld  
(Explanation for Linux 2.6) For processes running a real-time scheduling policy (policy below; see `sched_setscheduler(2)`), this is the negated scheduling priority, minus one; that is, a number in the range -2 to -100, corresponding to real-time priorities 1 to 99. For processes running under a non-real-time scheduling policy, this is the raw nice value (`setpriority(2)`) as represented in the kernel. The kernel stores nice values as numbers in the range 0 (high) to 39 (low), corresponding to the user-visible nice range of -20 to 19.
- (19) `nice` %ld  
The nice value (see `setpriority(2)`), a value in the range 19 (low priority) to -20 (high priority).
- (20) `num_threads` %ld  
Number of threads in this process (since Linux 2.6). Before kernel 2.6, this field was hard coded to 0 as a placeholder for an earlier removed field.
- (21) `itrealvalue` %ld  
The time in jiffies before the next SIGALRM is sent to the process due to an interval timer. Since kernel 2.6.17, this field is no longer maintained, and is hard coded as 0.
- (22) `starttime` %llu  
The time the process started after system boot. In kernels before Linux 2.6, this value was expressed in jiffies. Since Linux 2.6, the value is expressed in clock ticks (divide by `sysconf(_SC_CLK_TCK)`).  
  
The format for this field was %lu before Linux 2.6.
- (23) `vsiz` %lu  
Virtual memory size in bytes.
- (24) `rss` %ld  
Resident Set Size: number of pages the process has in real memory. This is just the pages which count toward text, data, or stack space. This does not include pages which have not been demand-loaded in, or which are swapped out.
- (25) `rsslim` %lu  
Current soft limit in bytes on the rss of the process; see the description of `RLIMIT_RSS` in `getrlimit(2)`.
- (26) `startcode` %lu [PT]  
The address above which program text can run.
- (27) `endcode` %lu [PT]  
The address below which program text can run.
- (28) `startstack` %lu [PT]  
The address of the start (i.e., bottom) of the stack.
- (29) `kstkesp` %lu [PT]  
The current value of ESP (stack pointer), as found in the kernel stack page for the process.
- (30) `kstkeip` %lu [PT]  
The current EIP (instruction pointer).
- (31) `signal` %lu  
The bitmap of pending signals, displayed as a decimal number. Obsolete, because it does not provide information on real-time signals; use `/proc/[pid]/status` instead.
- (32) `blocked` %lu  
The bitmap of blocked signals, displayed as a decimal number. Obsolete, because it does not provide information on real-time signals; use `/proc/[pid]/status` instead.
- (33) `sigignore` %lu  
The bitmap of ignored signals, displayed as a decimal number. Obsolete, because it does not provide information on real-time signals; use `/proc/[pid]/status` instead.
- (34) `sigcatch` %lu  
The bitmap of caught signals, displayed as a decimal number. Obsolete, because it does not provide information on real-time signals; use `/proc/[pid]/status` instead.

- (35) `wchan %lu [PT]`  
This is the "channel" in which the process is waiting. It is the address of a location in the kernel where the process is sleeping. The corresponding symbolic name can be found in `/proc/[pid]/wchan`.
- (36) `nswap %lu`  
Number of pages swapped (not maintained).
- (37) `cnswap %lu`  
Cumulative `nswap` for child processes (not maintained).
- (38) `exit_signal %d (since Linux 2.1.22)`  
Signal to be sent to parent when we die.
- (39) `processor %d (since Linux 2.2.8)`  
CPU number last executed on.
- (40) `rt_priority %u (since Linux 2.5.19)`  
Real-time scheduling priority, a number in the range 1 to 99 for processes scheduled under a real-time policy, or 0, for non-real-time processes (see `sched_setscheduler(2)`).
- (41) `policy %u (since Linux 2.5.19)`  
Scheduling policy (see `sched_setscheduler(2)`). Decode using the `SCHED_*` constants in `linux/sched.h`.  
  
The format for this field was `%lu` before Linux 2.6.22.
- (42) `delayacct_blkio_ticks %llu (since Linux 2.6.18)`  
Aggregated block I/O delays, measured in clock ticks (centiseconds).
- (43) `guest_time %lu (since Linux 2.6.24)`  
Guest time of the process (time spent running a virtual CPU for a guest operating system), measured in clock ticks (divide by `sysconf(_SC_CLK_TCK)`).
- (44) `cguest_time %ld (since Linux 2.6.24)`  
Guest time of the process's children, measured in clock ticks (divide by `sysconf(_SC_CLK_TCK)`).
- (45) `start_data %lu (since Linux 3.3) [PT]`  
Address above which program initialized and uninitialized (BSS) data are placed.
- (46) `end_data %lu (since Linux 3.3) [PT]`  
Address below which program initialized and uninitialized (BSS) data are placed.
- (47) `start_brk %lu (since Linux 3.3) [PT]`  
Address above which program heap can be expanded with `brk(2)`.
- (48) `arg_start %lu (since Linux 3.5) [PT]`  
Address above which program command-line arguments (`argv`) are placed.
- (49) `arg_end %lu (since Linux 3.5) [PT]`  
Address below program command-line arguments (`argv`) are placed.
- (50) `env_start %lu (since Linux 3.5) [PT]`  
Address above which program environment is placed.
- (51) `env_end %lu (since Linux 3.5) [PT]`  
Address below which program environment is placed.
- (52) `exit_code %d (since Linux 3.5) [PT]`  
The thread's exit status in the form reported by `waitpid(2)`.

```

## readProcIO - //proc//<pid >//io

/proc/[pid]/io (since kernel 2.6.20)

This file contains I/O statistics for the process, for example:

```

# cat /proc/3828/io
rchar: 323934931
wchar: 323929600
syscr: 632687
syscw: 632675
read_bytes: 0
write_bytes: 323932160
cancelled_write_bytes: 0

```

The fields are as follows:

rchar: characters read

The number of bytes which this task has caused to be read from storage. This is simply the sum of bytes which this process passed to read(2) and similar system calls. It includes things such as terminal I/O and is unaffected by whether or not actual physical disk I/O was required (the read might have been satisfied from pagecache).

wchar: characters written

The number of bytes which this task has caused, or shall cause to be written to disk. Similar caveats apply here as with rchar.

syscr: read syscalls

Attempt to count the number of read I/O operations-that is, system calls such as read(2) and pread(2).

syscw: write syscalls

Attempt to count the number of write I/O operations-that is, system calls such as write(2) and pwrite(2).

read\_bytes: bytes read

Attempt to count the number of bytes which this process really did cause to be fetched from the storage layer. This is accurate for block-backed filesystems.

write\_bytes: bytes written

Attempt to count the number of bytes which this process caused to be sent to the storage layer.

cancelled\_write\_bytes:

The big inaccuracy here is truncate. If a process writes 1MB to a file and then deletes the file, it will in fact perform no writeout. But it will have been accounted as having caused 1MB of write. In other words: this field represents the number of bytes which this process caused to not happen, by truncating pagecache. A task can cause "negative" I/O too. If this task truncates some dirty pagecache, some I/O which another task has been accounted for (in its write\\_bytes) will not be happening.

Note: In the current implementation, things are a bit racy on 32-bit systems: if process A reads process B's /proc/[pid]/io while process B is updating one of these 64-bit counters, process A could see an intermediate result.

Permission to access this file is governed by a ptrace access mode PTRACE\\_MODE\\_READ\\_FSCREDS check; see ptrace(2).

```

### 1.7.9 Cardano.BM.Data.Aggregated

#### Measurable

A **Measurable** may consist of different types of values. Time measurements are strict, so are *Bytes* which are externally measured. The real or integral numeric values are lazily linked, so we can decide later to drop them.

```

data Measurable = Microseconds {-# UNPACK #-} !Word64
  | Nanoseconds {-# UNPACK #-} !Word64
  | Seconds {-# UNPACK #-} !Word64
  | Bytes {-# UNPACK #-} !Word64
  | PureD Double
  | PureI Integer
  | Severity S.Severity
deriving (Eq, Read, Generic, ToJSON)

```

**Measurable** can be transformed to an integral value.

```

instance Ord Measurable where
  compare (Seconds a) (Seconds b) = compare a b
  compare (Microseconds a) (Microseconds b) = compare a b
  compare (Nanoseconds a) (Nanoseconds b) = compare a b
  compare (Seconds a) (Microseconds b) = compare (a * 1000000) b
  compare (Nanoseconds a) (Microseconds b) = compare a (b * 1000)
  compare (Seconds a) (Nanoseconds b) = compare (a * 1000000000) b
  compare (Microseconds a) (Nanoseconds b) = compare (a * 1000) b
  compare (Microseconds a) (Seconds b) = compare a (b * 1000000)
  compare (Nanoseconds a) (Seconds b) = compare a (b * 1000000000)
  compare (Bytes a) (Bytes b) = compare a b
  compare (PureD a) (PureD b) = compare a b
  compare (PureI a) (PureI b) = compare a b
  compare (Severity a) (Severity b) = compare a b
  compare (PureI a) (Seconds b) | a ≥ 0 = compare a (toInteger b)
  compare (PureI a) (Microseconds b) | a ≥ 0 = compare a (toInteger b)
  compare (PureI a) (Nanoseconds b) | a ≥ 0 = compare a (toInteger b)
  compare (PureI a) (Bytes b) | a ≥ 0 = compare a (toInteger b)
  compare (Seconds a) (PureI b) | b ≥ 0 = compare (toInteger a) b
  compare (Microseconds a) (PureI b) | b ≥ 0 = compare (toInteger a) b
  compare (Nanoseconds a) (PureI b) | b ≥ 0 = compare (toInteger a) b

```

```

compare (Bytes a)      (PureI b) | b ≥ 0 = compare (toInteger a) b
compare a@(PureD _) (PureI b)           = compare (getInteger a) b
compare (PureI a) b@(PureD _)           = compare a (getInteger b)
compare a b                               = error $ "cannot compare " ++ (showType a) ++ " " ++ (showType b)

```

**Measurable** can be transformed to an integral value.

```

getInteger :: Measurable → Integer
getInteger (Microseconds a) = toInteger a
getInteger (Nanoseconds a) = toInteger a
getInteger (Seconds a)     = toInteger a
getInteger (Bytes a)       = toInteger a
getInteger (PureI a)       = a
getInteger (PureD a)       = round a
getInteger (Severity a)    = toInteger (fromEnum a)

```

**Measurable** can be transformed to a rational value.

```

getDouble :: Measurable → Double
getDouble (Microseconds a) = fromIntegral a
getDouble (Nanoseconds a) = fromIntegral a
getDouble (Seconds a)     = fromIntegral a
getDouble (Bytes a)       = fromIntegral a
getDouble (PureI a)       = fromIntegral a
getDouble (PureD a)       = a
getDouble (Severity a)    = fromIntegral (fromEnum a)

```

It is a numerical value, thus supports functions to operate on numbers.

**instance Num Measurable where**

```

### 1.7.10 Cardano.BM.Data.AggregatedKind

#### AggregatedKind

This identifies the type of Aggregated.

```
data AggregatedKind = StatsAK
  | EwmaAK {alpha :: Double}
  deriving (Generic, Eq, Show, FromJSON, ToJSON, Read)
```

### 1.7.11 Cardano.BM.Data.Backend

#### Accepts a **LogObject**

Instances of this type class accept a **LogObject** and deal with it.

```
class IsEffectuator t a where
  effectuate :: t a → LogObject a → IO ()
  effectuatefrom :: forall s o (IsEffectuator s a) ⇒ t a → LogObject a → s a → IO ()
  default effectuatefrom :: forall s o (IsEffectuator s a) ⇒ t a → LogObject a → s a → IO ()
  effectuatefrom t nli _ = effectuate t nli
  handleOverflow :: t a → IO ()
```

### Declaration of a **Backend**

A backend is life-cycle managed, thus can be *realized* and *unrealized*.

```
class IsEffectuator t a ⇒ IsBackend t a where
  typeof    :: t a → BackendKind
  realize    :: Configuration → IO (t a)
  realizefrom :: forall s o (IsEffectuator s a) ⇒ Configuration → Trace IO a → s a → IO (t a)
  default realizefrom :: forall s o (IsEffectuator s a) ⇒ Configuration → Trace IO a → s a → IO (t a)
  realizefrom cfg _ _ = realize cfg
  unrealize :: t a → IO ()
```

### Backend

This data structure for a backend defines its behaviour as an **IsEffectuator** when processing an incoming message, and as an **IsBackend** for unrealizing the backend.

```
data Backend a = MkBackend
  { bEffectuate :: LogObject a → IO ()
  , bUnrealize :: IO ()
  }
```

#### 1.7.12 Cardano.BM.Data.BackendKind

##### BackendKind

This identifies the backends that can be attached to the **Switchboard**.

```
data BackendKind =
  AggregationBK
  | EditorBK
  | EKGViewBK
  | KatipBK
  | LogBufferBK
  | MonitoringBK
  | SwitchboardBK
  deriving (Generic, Eq, Ord, Show, ToJSON, FromJSON, Read)
```

#### 1.7.13 Cardano.BM.Data.Configuration

Data structure to help parsing configuration files.

##### Representation

```
type Port = Int
data Representation = Representation
  { minSeverity    :: Severity
  , rotation       :: Maybe RotationParameters
  , setupScribes   :: [ScribeDefinition]
  , defaultScribes :: [(ScribeKind, Text)]
  , setupBackends  :: [BackendKind]
```

```
,defaultBackends :: [BackendKind]
,hasEKG           :: Maybe Port
,hasGUI           :: Maybe Port
,options          :: HM.HashMap Text Object
}
deriving (Generic, Show, ToJSON, FromJSON)
```

## parseRepresentation

```
parseRepresentation :: FilePath → IO Representation
parseRepresentation fp = do
  repr :: Representation ← decodeFileThrow fp
  return $ implicit_fill_representation repr
```

after parsing the configuration representation we implicitly correct it.

```
implicit_fill_representation :: Representation → Representation
implicit_fill_representation =
  remove_ekgview_if_not_defined ∘
  filter_duplicates_from_backends ∘
  filter_duplicates_from_scribes ∘
  union_setup_and_usage_backends ∘
  add_ekgview_if_port_defined ∘
  add_katip_if_any_scribes
where
  filter_duplicates_from_backends r =
    r {setupBackends = mkUniq $ setupBackends r}
  filter_duplicates_from_scribes r =
    r {setupScribes = mkUniq $ setupScribes r}
  union_setup_and_usage_backends r =
    r {setupBackends = setupBackends r <> defaultBackends r}
  # ifdef ENABLE_EKG
    remove_ekgview_if_not_defined r =
      case hasEKG r of
        Nothing → r {defaultBackends = filter (λbk → bk ≠ EKGViewBK) (defaultBackends r)
                    ,setupBackends = filter (λbk → bk ≠ EKGViewBK) (setupBackends r)
                    }
        Just _ → r
    add_ekgview_if_port_defined r =
      case hasEKG r of
        Nothing → r
        Just _ → r {setupBackends = setupBackends r <> [EKGViewBK]}
  # else
    remove_ekgview_if_not_defined = id
    add_ekgview_if_port_defined = id
  # endif
  add_katip_if_any_scribes r =
    if (any ¬ [null $ setupScribes r, null $ defaultScribes r])
    then r {setupBackends = setupBackends r <> [KatipBK]}
    else r
```

```
mkUniq :: Ord a => [a] -> [a]
mkUniq = Set.toList o Set.fromList
```

### 1.7.14 Cardano.BM.Data.Counter

#### Counter

```
data Counter = Counter
  { cType :: CounterType
  , cName :: Text
  , cValue :: Measurable
  }
  deriving (Eq, Show, Generic, ToJSON)

data CounterType = MonotonicClockTime
  | MemoryCounter
  | StatInfo
  | IOCounter
  | NetCounter
  | CpuCounter
  | RTStats
  deriving (Eq, Show, Generic, ToJSON)

instance ToJSON Microsecond where
  toJSON = toJSON o toMicroseconds
  toEncoding = toEncoding o toMicroseconds
```

#### Names of counters

```
nameCounter :: Counter -> Text
nameCounter (Counter MonotonicClockTime _) = "Time-interval"
nameCounter (Counter MemoryCounter _) = "Mem"
nameCounter (Counter StatInfo _) = "Stat"
nameCounter (Counter IOCounter _) = "IO"
nameCounter (Counter NetCounter _) = "Net"
nameCounter (Counter CpuCounter _) = "Cpu"
nameCounter (Counter RTStats _) = "RTS"
```

#### CounterState

```
data CounterState = CounterState {
  csIdentifier :: Unique
  , csCounters :: [Counter]
  }
  deriving (Generic, ToJSON)

instance ToJSON Unique where
  toJSON = toJSON o hashUnique
  toEncoding = toEncoding o hashUnique

instance Show CounterState where
  show cs = (show o hashUnique) (csIdentifier cs)
    <> " => " <> (show $ csCounters cs)
```

**Difference between counters**

```

diffCounters :: [Counter] → [Counter] → [Counter]
diffCounters openings closings =
  getCountersDiff openings closings
where
  getCountersDiff :: [Counter]
    → [Counter]
    → [Counter]
  getCountersDiff as bs =
    let
      getName counter = nameCounter counter <> cName counter
      asNames = map getName as
      aPairs = zip asNames as
      bsNames = map getName bs
      bs' = zip bsNames bs
      bPairs = HM.fromList bs'
    in
      catMaybes $ (flip map) aPairs $ λ(name, Counter _ _ startValue) →
        case HM.lookup name bPairs of
          Nothing → Nothing
          Just counter → let endValue = cValue counter
                        in Just counter {cValue = endValue – startValue}

```

**1.7.15 Cardano.BM.Data.LogItem****LoggerName**

A **LoggerName** has currently type *Text*.

```
type LoggerName = Text
```

**Logging of outcomes with LogObject**

```

data LogObject a = LogObject
  { loName :: LoggerName
  , loMeta :: !LOMeta
  , loContent :: (LOContent a)
  }
deriving (Generic, Show, ToJSON)

```

Meta data for a **LogObject**. Text was selected over ThreadId in order to be able to use the logging system under SimM of ouroboros-network because ThreadId from Control.Concurrent lacks a Read instance.

```

data LOMeta = LOMeta {
  timestamp :: {-# UNPACK #-} !UTCTime
  , tid      :: {-# UNPACK #-} !Text
  , severity :: !Severity
  , privacy  :: !PrivacyAnnotation

```

```

}
deriving (Show)
instance ToJSON LOMeta where
  toJSON (LOMeta _tstamp _tid _sev _priv) =
    object [ "tstamp" . = _tstamp
            , "tid"      . = show _tid
            , "severity" . = show _sev
            , "privacy"  . = show _priv
            ]
mkLOMeta :: Severity → PrivacyAnnotation → IO LOMeta
mkLOMeta sev priv =
  LOMeta <$> getCurrentTime
    <*> (pack ◦ show <$> myThreadId)
    <*> pure sev
    <*> pure priv

```

Payload of a **LogObject**:

```

data LOContent a = LogMessage a
  | LogValue Text Measurable
  | ObserveOpen CounterState
  | ObserveDiff CounterState
  | ObserveClose CounterState
  | AggregatedMessage [(Text, Aggregated)]
  | MonitoringEffect (LogObject a)
  | Command CommandValue
  | KillPill
  deriving (Generic, Show, ToJSON)

```

Backends can enter commands to the trace. Commands will end up in the **Switchboard**, which will interpret them and take action.

```

data CommandValue = DumpBufferedTo BackendKind
  deriving (Generic, Show, ToJSON)

```

## Privacy annotation

```

data PrivacyAnnotation =
  Confidential -- confidential information - handle with care
  | Public -- indifferent - can be public.
  deriving (Show, Generic, ToJSON, FromJSON)

```

Data structure for annotating the severity and privacy of an object.

```

data PrivacyAndSeverityAnnotated a
  = PSA { psaSeverity :: !Severity
        , psaPrivacy :: !PrivacyAnnotation
        , psaPayload :: a
        }
  deriving (Show)

```

**1.7.16 Cardano.BM.Data.Observable****ObservableInstance**

```

data ObservableInstance = MonotonicClock
  | MemoryStats
  | ProcessStats
  | NetStats
  | IOStats
  | GhcRtsStats
  deriving (Generic, Eq, Show, FromJSON, ToJSON, Read)

```

**1.7.17 Cardano.BM.Data.Output****ScribeKind**

This identifies katip's scribes by type.

```

data ScribeKind = FileTextSK
  | FileJsonSK
  | StdoutSK
  | StderrSK
  | DevNullSK
  deriving (Generic, Eq, Ord, Show, Read, FromJSON, ToJSON)

```

**ScribeId**

A scribe is identified by **ScribeKind** *x* *Filename*

```

type ScribeId = Text -- (ScribeKind :: Filename)

```

**ScribePrivacy**

This declares if a scribe will be public (and must not contain sensitive data) or private.

```

data ScribePrivacy = ScPublic | ScPrivate
  deriving (Generic, Eq, Ord, Show, FromJSON, ToJSON)

```

**ScribeDefinition**

This identifies katip's scribes by type.

```

data ScribeDefinition = ScribeDefinition
  { scKind    :: ScribeKind
  , scName    :: Text
  , scPrivacy :: ScribePrivacy
  , scRotation :: Maybe RotationParameters
  }
  deriving (Generic, Eq, Ord, Show, ToJSON)
instance FromJSON ScribeDefinition where
  parseJSON (Object o) = do

```

```

kind    ← o.: "scKind"
name    ← o.: "scName"
mayPrivacy ← o.:? "scPrivacy"
rotation ← o.:? "scRotation"
return $ ScribeDefinition
  {scKind    = kind
  ,scName    = name
  ,scPrivacy = fromMaybe ScPublic mayPrivacy
  ,scRotation = rotation
  }
parseJSON invalid = typeMismatch "ScribeDefinition" invalid

```

### 1.7.18 Cardano.BM.Data.Rotation

#### RotationParameters

```

data RotationParameters = RotationParameters
  {rpLogLimitBytes :: !Word64 -- max size of file in bytes
  ,rpMaxAgeHours   :: !Word   -- hours
  ,rpKeepFilesNum  :: !Word   -- number of files to keep
  } deriving (Generic, Show, Eq, Ord, FromJSON, ToJSON)

```

### 1.7.19 Cardano.BM.Data.Severity

#### Severity

The intended meaning of severity codes:

Debug *detailed information about values and decision flow* Info general information of events; progressing properly Notice *needs attention; something – progressing properly* Warning may continue into an error condition if continued Error *unexpected set of event or condition occurred* Critical error condition causing degrade of operation Alert *a subsystem is no longer operating correctly, likely requires man* at this point, the system can never progress without additional intervention

We were informed by the Syslog taxonomy: [https://en.wikipedia.org/wiki/Syslog#Severity\\_level](https://en.wikipedia.org/wiki/Syslog#Severity_level)

```

data Severity = Debug
  | Info
  | Notice
  | Warning
  | Error
  | Critical
  | Alert
  | Emergency
  deriving (Show, Eq, Ord, Enum, Generic, ToJSON, Read)

instance FromJSON Severity where
  parseJSON = withText "severity" $ \case
    "Debug"    → pure Debug
    "Info"     → pure Info
    "Notice"   → pure Notice
    "Warning"  → pure Warning
    "Error"    → pure Error
    "Critical" → pure Critical

```

```

"Alert"      → pure Alert
"Emergency"  → pure Emergency

### 1.7.20 Cardano.BM.Data.SubTrace

#### SubTrace

```

data NameSelector = Exact Text | StartsWith Text | EndsWith Text | Contains Text
  deriving (Generic, Show, FromJSON, ToJSON, Read, Eq)
data DropName     = Drop NameSelector
  deriving (Generic, Show, FromJSON, ToJSON, Read, Eq)
data UnhideNames = Unhide [NameSelector]
  deriving (Generic, Show, FromJSON, ToJSON, Read, Eq)

data SubTrace = Neutral
  | UntimedTrace
  | NoTrace
  | TeeTrace LoggerName
  | FilterTrace [(DropName, UnhideNames)]
  | DropOpening
  | ObservableTrace [ObservableInstance]
  deriving (Generic, Show, Read, Eq)

instance FromJSON SubTrace where
  parseJSON = withObject "" $ \o → do
    subtrace :: Text ← o .: "subtrace"
    case subtrace of
      "Neutral"      → return $ Neutral
      "UntimedTrace" → return $ UntimedTrace
      "NoTrace"      → return $ NoTrace
      "TeeTrace"     → TeeTrace <$> o .: "contents"
      "FilterTrace"  → FilterTrace <$> o .: "contents"
      "DropOpening"  → return $ DropOpening
      "ObservableTrace" → ObservableTrace <$> o .: "contents"
      _              → error "cannot parse such an expression!"

instance ToJSON SubTrace where
  toJSON Neutral      = object [ "subtrace" . = String "Neutral" ]
  toJSON UntimedTrace = object [ "subtrace" . = String "UntimedTrace" ]
  toJSON NoTrace      = object [ "subtrace" . = String "NoTrace" ]
  toJSON (TeeTrace name) = object [ "subtrace" . = String "TeeTrace" , "contents" . = toJSON name ]
  toJSON (FilterTrace dus) = object [ "subtrace" . = String "FilterTrace" , "contents" . = toJSON dus ]
  toJSON DropOpening   = object [ "subtrace" . = String "DropOpening" ]
  toJSON (ObservableTrace os) = object [ "subtrace" . = String "ObservableTrace", "contents" . = toJSON os ]

```

### 1.7.21 Cardano.BM.Data.Trace

#### Trace

A **Trace**  $m\ a$  is a **Tracer**  $m$  (**LogObject**  $a$ ).

```
type Trace m a = Tracer m (LogObject a)
```

### 1.7.22 Cardano.BM.Data.Tracer

This module extends the basic **Tracer** with one that keeps a list of context names to create the basis for **Trace** which accepts messages from a Tracer and ends in the **Switchboard** for further processing of the messages.

#### ToLogObject - transforms a logged item to LogObject

The function **toLogObject** can be specialized for various environments

```

class Monad m => ToLogObject m where
  toLogObject :: ToObject a => Tracer m (LogObject a) -> Tracer m a
instance ToLogObject IO where
  toLogObject :: ToObject a => Tracer IO (LogObject a) -> Tracer IO a
  toLogObject tr = Tracer $ \a -> do
    lo <- LogObject <$> pure ""
    <*> (mkLOMeta Debug Public)
    <*> pure (LogMessage a)
    traceWith tr lo

```

To be placed in *ouroboros-network*

```

instance (MonadFork m, MonadTimer m) => ToLogObject m where
  toLogObject tr = Tracer $ \a -> do
    lo <- LogObject <$> pure ""
    <*> (LOMeta <$> getMonotonicTime -- must be evaluated at the calling site
    <*> (pack o show <$> myThreadId)

```

```

    < * > pure Debug
    < * > pure Public)
  < * > pure (LogMessage a)
  traceWith tr lo

```

### **ToObject - transforms a logged item to JSON**

Katip requires JSON objects to be logged as context. This typeclass provides a default instance which uses *ToJSON* and produces an empty object if 'toJSON' results in any type other than *Object*. If you have a type you want to log that produces an Array or Number for example, you'll want to write an explicit instance here. You can trivially add a *ToObject* instance for something with a *ToJSON* instance like:

```

instance ToObject Foo

class ToJSON a => ToObject a where
  toObject :: a -> Object
  default toObject :: a -> Object
  toObject v = case toJSON v of
    Object o -> o
    s@(String _) -> HM.singleton "string" s
    _ -> mempty
instance ToObject () where
  toObject _ = mempty
instance ToObject String
instance ToObject Text
instance ToJSON a => ToObject (LogObject a)
instance ToJSON a => ToObject (LOContent a)

```

### 1.7.23 Cardano.BM.Configuration

see **Cardano.BM.Configuration.Model** for the implementation.

```

getOptionOrDefault :: CM.Configuration -> Text -> Text -> IO (Text)
getOptionOrDefault cg name def = do
  opt <- CM.getOption cg name
  case opt of
    Nothing -> return def
    Just o -> return o

```

### 1.7.24 Cardano.BM.Configuration.Model

#### **Configuration.Model**

```

type ConfigurationMVar = MVar ConfigurationInternal
newtype Configuration = Configuration
  {getCG :: ConfigurationMVar}
-- Our internal state; see -"Configuration model"-
data ConfigurationInternal = ConfigurationInternal

```

<<Model>> Configuration	
cgMinSeverity	: Severity

} deriving (Show, Eq)

```

### Backends configured in the **Switchboard**

For a given context name return the list of backends configured, or, in case no such configuration exists, return the default backends.

```

getBackends :: Configuration → LoggerName → IO [BackendKind]
getBackends configuration name = do
  cg ← readMVar $ getCG configuration
  let outs = HM.lookup name (cgMapBackend cg)
  case outs of
    Nothing → return (cgDefBackendKs cg)
    Just os → return os

getDefaultBackends :: Configuration → IO [BackendKind]
getDefaultBackends configuration =
  cgDefBackendKs < $ > (readMVar $ getCG configuration)

setDefaultBackends :: Configuration → [BackendKind] → IO ()
setDefaultBackends configuration bes =
  modifyMVar_ (getCG configuration) $ \cg →
    return cg {cgDefBackendKs = bes}

setBackends :: Configuration → LoggerName → Maybe [BackendKind] → IO ()
setBackends configuration name be =
  modifyMVar_ (getCG configuration) $ \cg →
    return cg {cgMapBackend = HM.alter (\_ → be) name (cgMapBackend cg)}

```

### Backends to be setup by the **Switchboard**

Defines the list of **Backends** that need to be setup by the **Switchboard**.

```

setSetupBackends :: Configuration → [BackendKind] → IO ()
setSetupBackends configuration bes =
  modifyMVar_ (getCG configuration) $ \cg →
    return cg {cgSetupBackends = bes}

getSetupBackends :: Configuration → IO [BackendKind]
getSetupBackends configuration =
  cgSetupBackends < $ > (readMVar $ getCG configuration)

```

### Scribes configured in the **Log** backend

For a given context name return the list of scribes to output to, or, in case no such configuration exists, return the default scribes to use.

```

getScribes :: Configuration → LoggerName → IO [ScribeId]
getScribes configuration name = do
  cg ← readMVar (getCG configuration)

```

```

(updateCache, scribes) ← do
  let defs = cgDefScribes cg
  let mapscribes = cgMapScribe cg
  let find_s lname = case HM.lookup lname mapscribes of
    Nothing →
      case dropToDot lname of
        Nothing → defs
        Just lname' → find_s lname'
    Just os → os
  let outs = HM.lookup name (cgMapScribeCache cg)
  -- look if scribes are already cached
  return $ case outs of
    -- if no cached scribes found; search the appropriate scribes that
    -- they must inherit and update the cached map
    Nothing → (True, find_s name)
    Just os → (False, os)
  when updateCache $ setCachedScribes configuration name $ Just scribes
  return scribes

dropToDot :: Text → Maybe Text
dropToDot ts = dropToDot' (T.breakOnEnd "." ts)
  where
    dropToDot' (_, "") = Nothing
    dropToDot' (name', _) = Just $ T.dropWhileEnd (≡ ' . ') name'

getCacheScribes :: Configuration → LoggerName → IO (Maybe [ScribeId])
getCacheScribes configuration name = do
  cg ← readMVar $ getCG configuration
  return $ HM.lookup name $ cgMapScribeCache cg

setScribes :: Configuration → LoggerName → Maybe [ScribeId] → IO ()
setScribes configuration name scribes =
  modifyMVar_ (getCG configuration) $ \cg →
    return cg {cgMapScribe = HM.alter (\_ → scribes) name (cgMapScribe cg)}

setCachedScribes :: Configuration → LoggerName → Maybe [ScribeId] → IO ()
setCachedScribes configuration name scribes =
  modifyMVar_ (getCG configuration) $ \cg →
    return cg {cgMapScribeCache = HM.alter (\_ → scribes) name (cgMapScribeCache cg)}

setDefaultScribes :: Configuration → [ScribeId] → IO ()
setDefaultScribes configuration scs =
  modifyMVar_ (getCG configuration) $ \cg →
    return cg {cgDefScribes = scs}

```

### Scribes to be setup in the **Log** backend

Defines the list of Scribes that need to be setup in the **Log** backend.

```

setSetupScribes :: Configuration → [ScribeDefinition] → IO ()
setSetupScribes configuration sds =
  modifyMVar_ (getCG configuration) $ \cg →
    return cg {cgSetupScribes = sds}

getSetupScribes :: Configuration → IO [ScribeDefinition]

```

```
getSetupScribes configuration =
  cgSetupScribes < $ > readMVar (getCG configuration)
```

### AggregatedKind to define the type of measurement

For a given context name return its **AggregatedKind** or in case no such configuration exists, return the default **AggregatedKind** to use.

```
getAggregatedKind :: Configuration → LoggerName → IO AggregatedKind
getAggregatedKind configuration name = do
  cg ← readMVar $ getCG configuration
  let outs = HM.lookup name (cgMapAggregatedKind cg)
  case outs of
    Nothing → return $ cgDefAggregatedKind cg
    Just os → return $ os

setDefaultAggregatedKind :: Configuration → AggregatedKind → IO ()
setDefaultAggregatedKind configuration defAK =
  modifyMVar_ (getCG configuration) $ \cg →
    return cg {cgDefAggregatedKind = defAK}

setAggregatedKind :: Configuration → LoggerName → Maybe AggregatedKind → IO ()
setAggregatedKind configuration name ak =
  modifyMVar_ (getCG configuration) $ \cg →
    return cg {cgMapAggregatedKind = HM.alter (\_ → ak) name (cgMapAggregatedKind cg)}
```

### Access port numbers of EKG, GUI

```
getEKGport :: Configuration → IO Int
getEKGport configuration =
  cgPortEKG < $ > (readMVar $ getCG configuration)

setEKGport :: Configuration → Int → IO ()
setEKGport configuration port =
  modifyMVar_ (getCG configuration) $ \cg →
    return cg {cgPortEKG = port}

getGUIport :: Configuration → IO Int
getGUIport configuration =
  cgPortGUI < $ > (readMVar $ getCG configuration)

setGUIport :: Configuration → Int → IO ()
setGUIport configuration port =
  modifyMVar_ (getCG configuration) $ \cg →
    return cg {cgPortGUI = port}
```

### Options

```
getOption :: Configuration → Text → IO (Maybe Text)
getOption configuration name = do
  cg ← readMVar $ getCG configuration
  case HM.lookup name (cgOptions cg) of
    Nothing → return Nothing
    Just o → return $ Just $ pack $ show o
```

### Global setting of minimum severity

```

minSeverity :: Configuration → IO Severity
minSeverity configuration =
  cgMinSeverity < $ > (readMVar $ getCG configuration)
setMinSeverity :: Configuration → Severity → IO ()
setMinSeverity configuration sev =
  modifyMVar_ (getCG configuration) $ \cg →
    return cg {cgMinSeverity = sev}

```

### Relation of context name to minimum severity

```

inspectSeverity :: Configuration → Text → IO (Maybe Severity)
inspectSeverity configuration name = do
  cg ← readMVar $ getCG configuration
  return $ HM.lookup name (cgMapSeverity cg)
setSeverity :: Configuration → Text → Maybe Severity → IO ()
setSeverity configuration name sev =
  modifyMVar_ (getCG configuration) $ \cg →
    return cg {cgMapSeverity = HM.alter (\_ → sev) name (cgMapSeverity cg)}

```

### Relation of context name to SubTrace

A new context may contain a different type of **Trace**. The function **appendName** will look up the **SubTrace** for the context's name.

```

findSubTrace :: Configuration → Text → IO (Maybe SubTrace)
findSubTrace configuration name = do
  cg ← readMVar $ getCG configuration
  return $ HM.lookup name (cgMapSubtrace cg)
setSubTrace :: Configuration → Text → Maybe SubTrace → IO ()
setSubTrace configuration name trafo =
  modifyMVar_ (getCG configuration) $ \cg →
    return cg {cgMapSubtrace = HM.alter (\_ → trafo) name (cgMapSubtrace cg)}

```

### Monitors

```

Just (
  fromList [
    ("chain.creation.block", Array [
      Object (fromList [ ("monitor", String "((time > (23 s)) Or (time < (17 s)))"]),
      Object (fromList [ ("actions", Array [
        String "AlterMinSeverity \"chain.creation\" Debug" ])]))
    ], ("#aggregation.critproc.observable", Array [
      Object (fromList [ ("monitor", String "(mean >= (42))"]),
      Object (fromList [ ("actions", Array [
        String "CreateMessage \"exceeded\" \"the observable has been too long too high!\",
        String "AlterGlobalMinSeverity Info" ])]))
    ]))

```

```

getMonitors :: Configuration → IO (HM.HashMap LoggerName (MEvExpr,[MEvAction]))
getMonitors configuration = do
  cg ← readMVar $ getCG configuration
  return (cgMonitors cg)

```

### Parse configuration from file

Parse the configuration into an internal representation first. Then, fill in **Configuration** after refinement.

```

    ,scKind = DevNullSK
    ,scPrivacy = ScPublic
    ,scRotation = Nothing
  }
]
  CM.setDefaultScribes c [ "NullSK::nooutput" ]
  return c

```

## 1.7.26 Cardano.BM.Output.Switchboard

### Switchboard

We are using an *MVar* because we spawn a set of backends that may try to send messages to the switchboard before it is completely setup.

```

type SwitchboardMVar a = MVar (SwitchboardInternal a)
newtype Switchboard a = Switchboard
  { getSB :: SwitchboardMVar a }
data SwitchboardInternal a = SwitchboardInternal
  { sbQueue    :: TBQ.TBQueue (LogObject a)
  , sbDispatch :: Async.Async ()
  , sbLogBuffer :: Cardano.BM.Output ◦ LogBuffer.LogBuffer a
  }

```

### Trace that forwards to the Switchboard

Every **Trace** ends in the **Switchboard** which then takes care of dispatching the messages to the selected backends.

This **Tracer** will forward all messages unconditionally to the **Switchboard**. (currently disabled)

```
mainTrace :: IsEffectuator eff a ⇒ eff a → Tracer IO (LogObject a)
mainTrace = Tracer ∘ effectuate
```

This **Tracer** will apply to every message the severity filter as defined in the **Configuration**.

```
mainTraceConditionally :: IsEffectuator eff a ⇒ Configuration → eff a → Tracer IO (LogObject a)
mainTraceConditionally config eff = Tracer $ λitem@(LogObject logername meta _) → do
  passSevFilter ← testSeverity logername meta
  passSubTrace ← testSubTrace logername item
  if passSevFilter ∧ passSubTrace
  then effectuate eff item
  else return ()
where
  testSeverity :: LoggerName → LOMeta → IO Bool
  testSeverity logername meta = do
    globminsev ← liftIO $ Config.minSeverity config
    globnamesev ← liftIO $ Config.inspectSeverity config logername
    let minsev = max globminsev $ fromMaybe Debug globnamesev
    return $ (severity meta) ≥ minsev
  testSubTrace :: LoggerName → LogObject a → IO Bool
  testSubTrace logername lo = do
    subtrace ← fromMaybe Neutral < $ > Config.findSubTrace config logername
    return $ testSubTrace' lo subtrace
  testSubTrace' :: LogObject a → SubTrace → Bool
  testSubTrace' _ NoTrace = False
  testSubTrace' (LogObject _ _ (ObserveOpen _)) DropOpening = False
  testSubTrace' (LogObject loname _ (LogValue vname _)) (FilterTrace filters) = evalFilters filters (loname vname)
  testSubTrace' (LogObject loname _ _) (FilterTrace filters) = evalFilters filters loname
  testSubTrace' _ _ = True -- fallback: all pass
```

### Process incoming messages

Incoming messages are put into the queue, and then processed by the dispatcher. The switchboard will never block when processing incoming messages ("eager receiver").

The queue is initialized and the message dispatcher launched.

```
instance IsEffectuator Switchboard a where
  effectuate switchboard item = do
    let writequeue :: TBQ.TBQueue (LogObject a) → LogObject a → IO ()
    writequeue q i = do
      nocapacity ← atomically $ TBQ.isFullTBQueue q
      if nocapacity
      then handleOverflow switchboard
      else atomically $ TBQ.writeTBQueue q i
    sb ← readMVar (getSB switchboard)
    writequeue (sbQueue sb) item
```

```

handleOverflow _ = TIO.hPutStrLn stderr "Error: Switchboard's queue full, dropping log item"

instead of 'writequeue ...':
  evalMonitoringAction config item >>=
    mapM_ (writequeue (sbQueue sb))
evalMonitoringAction :: Configuration → LogObject a → m [LogObject a]
evalMonitoringAction c item = return [item]
  -- let action = LogObject loName=(loName item) <> ".action", loContent=LogMessage .
  -- return (action : item)

```

### Switchboard implements Backend functions

## MockSwitchboard

**MockSwitchboard** is useful for tests since it keeps the **LogObjects** to be output in a list.

```
newtype MockSwitchboard a = MockSB (TVar [LogObject a])
```

```
instance IsEffectuator MockSwitchboard a where
  effectuate (MockSB tvar) item = atomically $ modifyTVar tvar ((:) item)
  handleOverflow _ = pure ()
```

### traceMock

A **Tracer** which forwards **LogObjects** to **MockSwitchboard** simulating functionality of **mainTraceConditionally**

```
traceMock :: MockSwitchboard a → Config.Configuration → Tracer IO (LogObject a)
traceMock ms config =
  Tracer $ \item@(LogObject loggename _) → do
    traceWith mainTrace item
    subTrace ← fromMaybe Neutral < $ > Config.findSubTrace config loggename
    case subTrace of
      TeeTrace secName →
        traceWith mainTrace item {loName = secName}
      _ → return ()
  where
    mainTrace = mainTraceConditionally config ms
```

### 1.7.27 Cardano.BM.Output.Log

#### Internal representation

```
type LogMVar = MVar LogInternal
newtype Log a = Log
  { getK :: LogMVar }
data LogInternal = LogInternal

### 1.7.28 Cardano.BM.Output.LogBuffer

#### Structure of LogBuffer

```

newtype LogBuffer a = LogBuffer
  { getLogBuf :: LogBufferMVar a }
type LogBufferMVar a = MVar (LogBufferInternal a)
data LogBufferInternal a = LogBufferInternal
  { logBuffer :: LogBufferMap a
  }

```

#### Relation from log context name to log item

We keep the latest **LogObject** from a log context in a *HashMap*.

```

type LogBufferMap a = HM.HashMap LoggerName (LogObject a)

```

#### Read out the latest **LogObjects**

```

readBuffer :: LogBuffer a → IO [(LoggerName, LogObject a)]
readBuffer buffer =
  withMVar (getLogBuf buffer) $ λcurrentBuffer →
    return $ HM.toList $ logBuffer currentBuffer

```

#### LogBuffer is an effectuator

Function *effectuate* is called to pass in a **LogObject** for log buffering.

```

instance IsEffectuator LogBuffer a where
  effectuate buffer lo@(LogObject logname _lmeta (LogValue lvname _lvalue)) = do
    modifyMVar_ (getLogBuf buffer) $ λcurrentBuffer →
      return $ LogBufferInternal $ HM.insert ("#buffered." <> logname <> "." <> lvname) lo $ logBuffer c
  effectuate buffer lo@(LogObject logname _lmeta _logitem) = do
    modifyMVar_ (getLogBuf buffer) $ λcurrentBuffer →
      return $ LogBufferInternal $ HM.insert ("#buffered." <> logname) lo $ logBuffer currentBuffer
  handleOverflow _ = TIO.hPutStrLn stderr "Notice: overflow in LogBuffer, dropping log items"

```

#### LogBuffer implements Backend functions

##### LogBuffer is an IsBackend

```

instance IsBackend LogBuffer a where
  typeOf _ = LogBufferBK
  realize _ = do
    let emptyBuffer = LogBufferInternal HM.empty
    LogBuffer <$> newMVar emptyBuffer
  unrealize _ = return ()

```

### 1.7.29 Cardano.BM.Output.EKGView

#### Structure of EKGView

```

type EKGViewMVar a = MVar (EKGViewInternal a)
newtype EKGView a = EKGView
    {getEV :: EKGViewMVar a}
data EKGViewInternal a = EKGViewInternal
    {evQueue :: TBQ.TBQueue (Maybe (LogObject a))
    ,evLabels :: EKGViewMap
    ,evServer :: Server
    }

```

#### Relation from variable name to label handler

We keep the label handlers for later update in a *HashMap*.

```

type EKGViewMap = HM.HashMap Text Label.Label

```

#### Internal Trace

This is an internal **Trace**, named "#ekgview", which can be used to control the messages that are being displayed by EKG.

```

ekgTrace :: ToObject a => EKGView a -> Configuration -> IO (Trace IO a)
ekgTrace ekg _c = do
    let basetrace = ekgTrace' ekg
    Trace.appendName "#ekgview" basetrace
where
    ekgTrace' :: ToObject a => EKGView a -> Tracer IO (LogObject a)
    ekgTrace' ekgview = Tracer $ \lo@(LogObject lname _ ->) -> do
        let setlabel :: Text -> Text -> EKGViewInternal a -> IO (Maybe (EKGViewInternal a))
        setlabel name label ekg_i@(EKGViewInternal _ labels server) =
            case HM.lookup name labels of
                Nothing -> do
                    ekghdl <- getLabel name server
                    Label.set ekghdl label
                    return $ Just $ ekg_i {evLabels = HM.insert name ekghdl labels}
                Just ekghdl -> do
                    Label.set ekghdl label
                    return Nothing
    update :: ToObject a => LogObject a -> EKGViewInternal a -> IO (Maybe (EKGViewInternal a))

  effectuate ev $ LogObject "test.monitor023" meta (LogMessage (LogItem Public Warning "!!!! ALAR

```

### 1.7.30 Cardano.BM.Output.Editor

This simple configuration editor is accessible through a browser on <http://127.0.0.1:13789>, or whatever port has been set in the configuration.

A number of maps that relate logging context name to behaviour can be changed. And, most importantly, the global minimum severity that defines the filtering of log messages.

#### links

The GUI is built on top of *Threepenny-GUI* (<http://hackage.haskell.org/package/threepenny-gui>). The appearance is due to *w3-css* (<https://www.w3schools.com/w3css>).

#### Structure of Editor

```

type EditorMVar a = MVar (EditorInternal a)
newtype Editor a = Editor
  { getEd :: EditorMVar a }
data ToObject a ⇒ EditorInternal a = EditorInternal
  { edSBtrace :: Trace IO a
  , edThread :: Async.Async ()
  , edBuffer :: LogBuffer a
  }

```

### **Editor** implements **Backend** functions

**Editor** is an **IsBackend**

```

instance ToObject a ⇒ IsBackend Editor a where
  typeOf _ = EditorBK

```

```

realize _ = error "Editor cannot be instantiated by 'realize'"
realizefrom config sbtrace _ = do
  gref ← newEmptyMVar
  let gui = Editor gref
  port ← getGUIport config
  when (port ≤ 0) $ error "cannot create GUI"
  -- local LogBuffer

### 1.7.31 Cardano.BM.Output.Aggregation

#### Internal representation

```

type AggregationMVar a = MVar (AggregationInternal a)
newtype Aggregation a = Aggregation
  { getAg :: AggregationMVar a }
data AggregationInternal a = AggregationInternal
  { agQueue :: TBQ.TBQueue (Maybe (LogObject a))
  , agDispatch :: Async.Async ()
  }

```

#### Relation from context name to aggregated statistics

We keep the aggregated values (**Aggregated**) for a named context in a *HashMap*.

```

type AggregationMap = HM.HashMap Text AggregatedExpanded

```

#### Info for Aggregated operations

Apart from the **Aggregated** we keep some valuable info regarding to them; such as when was the last time it was sent.

```

type Timestamp = Word64
data AggregatedExpanded = AggregatedExpanded
  { aeAggregated :: !Aggregated
  , aeResetAfter :: !(Maybe Int)
  , aeLastSent :: {-# UNPACK #-} !Timestamp
  }

```

#### **Aggregation** implements *effectuate*

**Aggregation** is an **IsEffectuator** Enter the log item into the **Aggregation** queue.

```

instance IsEffectuator Aggregation a where
  effectuate agg item = do
    ag ← readMVar (getAg agg)
    nocapacity ← atomically $ TBQ.isFullTBQueue (agQueue ag)
    if nocapacity
    then handleOverflow agg
    else atomically $ TBQ.writeTBQueue (agQueue ag) $! Just item
  handleOverflow _ = TIO.hPutStrLn stderr "Notice: Aggregation's queue full, dropping log it

```

**Aggregation implements Backend functions****Aggregation** is an **IsBackend**

```

instance IsBackend Aggregation a where

```

### Update aggregation

We distinguish an uninitialized from an already initialized aggregation. The latter is properly initialized.

We use Welford's online algorithm to update the estimation of mean and variance of the sample statistics. (see [https://en.wikipedia.org/wiki/Algorithms\\_for\\_calculating\\_variance#Welford's](https://en.wikipedia.org/wiki/Algorithms_for_calculating_variance#Welford's_algorithm)

```

updateAggregation :: Measurable → Aggregated → LOMeta → Maybe Int → Aggregated
updateAggregation v (AggregatedStats s) lme resetAfter =
  let count = fcount (fbasic s)
      reset = maybe False (count ≥) resetAfter

```

```

in
if reset
then
  singletonStats v
else
  AggregatedStats $! Stats {flast = v
    ,fold = mkTimestamp
    ,fbasic = updateBaseStats (count ≥ 1) v (fbasic s)
    ,fdelta = updateBaseStats (count ≥ 2) (v - flast s) (fdelta s)
    ,ftimed = updateBaseStats (count ≥ 2) (mkTimestamp - fold s) (ftimed s)
  }
where
mkTimestamp = utc2ns (tstamp lme)
utc2ns (UTCTime days secs) =
  let yearsecs :: Rational
      yearsecs = 365 * 24 * 3600
      rdays, rsecs :: Rational
      rdays = toRational $ toModifiedJulianDay days
      rsecs = toRational secs
      s2ns = 1000000000
  in
    Nanoseconds $ round $ (fromRational $ s2ns * rsecs + rdays * yearsecs :: Double)
updateAggregation v (AggregatedEWMA e) _ _ = AggregatedEWMA $! ewma e v
updateBaseStats :: Bool → Measurable → BaseStats → BaseStats
updateBaseStats False _ s = s {fcount = fcount s + 1}
updateBaseStats True v s =
  let newcount = fcount s + 1
      newvalue = getDouble v
      delta = newvalue - fsum_A s
      dincr = (delta / fromIntegral newcount)
      delta2 = newvalue - fsum_A s - dincr
  in
    BaseStats {fmin = min (fmin s) v
      ,fmax = max v (fmax s)
      ,fcount = newcount
      ,fsum_A = fsum_A s + dincr
      ,fsum_B = fsum_B s + (delta * delta2)
    }

```

### Calculation of EWMA

Following [https://en.wikipedia.org/wiki/Moving\\_average#Exponential\\_moving\\_average](https://en.wikipedia.org/wiki/Moving_average#Exponential_moving_average) we calculate the exponential moving average for a series of values  $Y_t$  according to:

$$S_t = \begin{cases} Y_1, & t = 1 \\ \alpha \cdot Y_t + (1 - \alpha) \cdot S_{t-1}, & t > 1 \end{cases}$$

The pattern matching below ensures that the **EWMA** will start with the first value passed in, and will not change type, once determined.

```
ewma :: EWMA → Measurable → EWMA
```

```

ewma (EmptyEWMA a) v = EWMA a v
ewma (EWMA a s@(Microseconds _)) y@(Microseconds _) =
  EWMA a $ Microseconds $ round $ a * (getDouble y) + (1 - a) * (getDouble s)
ewma (EWMA a s@(Seconds _)) y@(Seconds _) =
  EWMA a $ Seconds $ round $ a * (getDouble y) + (1 - a) * (getDouble s)
ewma (EWMA a s@(Bytes _)) y@(Bytes _) =
  EWMA a $ Bytes $ round $ a * (getDouble y) + (1 - a) * (getDouble s)
ewma (EWMA a (PureI s)) (PureI y) =
  EWMA a $ PureI $ round $ a * (fromInteger y) + (1 - a) * (fromInteger s)
ewma (EWMA a (PureD s)) (PureD y) =
  EWMA a $ PureD $ a * y + (1 - a) * s
ewma _ _ = error "Cannot average on values of different type"

```

### 1.7.32 Cardano.BM.Output.Monitoring

#### Structure of Monitoring

```

type MonitorMVar a = MVar (MonitorInternal a)
newtype Monitor a = Monitor
  { getMon :: MonitorMVar a }
data MonitorInternal a = MonitorInternal
  { monQueue :: TBQ.TBQueue (Maybe (LogObject a))
  }

```

#### Relation from context name to monitoring state

We remember the state of each monitored context name.

```

data MonitorState = MonitorState {
  _expression :: MEvExpr
  , _actions   :: [MEvAction]
  , _environment :: Environment
  }
type MonitorMap = HM.HashMap LoggerName MonitorState

```

#### Monitor view is an effectuator

Function *effectuate* is called to pass in a **LogObject** for monitoring.

```

instance IsEffectuator Monitor a where
  effectuate monitor item = do

```

# Chapter 2

## Testing

### 2.1 Test coverage

Test coverage is calculated as the fraction of functions which are called from test routines. This percentage is calculated by the tool *hpc* with a call to

```
cabal new-test
```

Add to a local `cabal.project.local` file these lines:

```
tests:           True
coverage:        True
library-coverage: True
```

### 2.2 Test main entry point

```

## 2.3 Test case generation

### 2.3.1 instance Arbitrary Aggregated

We define an instance of *Arbitrary* for an **Aggregated** which lets *QuickCheck* generate arbitrary instances of **Aggregated**. For this an arbitrary list of *Integer* is generated and this list is aggregated into a structure of **Aggregated**.

```

instance Arbitrary Aggregated where
  arbitrary = do
    vs' ← arbitrary :: Gen [Integer]
    let vs = 42 : 17 : vs'
        ds = map (λ(a,b) → a - b) $ zip vs (tail vs)
        (m1,s1) = updateMeanVar $ map fromInteger vs
        (m2,s2) = updateMeanVar $ map fromInteger ds
        mkBasicStats = BaseStats
          (PureI (minimum vs))
          (PureI (maximum vs))
          (fromIntegral $ length vs)
          (m1)
          (s1)
        mkDeltaStats = BaseStats
          (PureI (minimum ds))
          (PureI (maximum ds))
          (fromIntegral $ length ds)
          (m2)
          (s2)
        mkTimedStats = BaseStats
          (Nanoseconds 0)
          (Nanoseconds 0)
          (0)
          (0)
          (0)

```

```

return $ AggregatedStats (Stats
  (PureI (last vs))
  (Nanoseconds 0)
  mkBasicStats
  mkDeltaStats
  mkTimedStats)

```

Estimators for mean and variance must be updated the same way as in the code.

```

updateMeanVar :: [Double] → (Double, Double)
updateMeanVar [] = (0, 0)
updateMeanVar (val : vals) = updateMeanVar' (val, 0) 1 vals
  where
    updateMeanVar' (m, s) _ [] = (m, s)
    updateMeanVar' (m, s) cnt (a : r) =
      let delta = a - m
          newcount = cnt + 1
          m' = m + (delta / newcount)
          s' = s + (delta * (a - m'))
      in
        updateMeanVar' (m', s') newcount r

```

## 2.4 Tests

### 2.4.1 Testing aggregation

```

### Control tracing in a hierarchy of **Traces**

We can lay out traces in a hierarchical manner, that the children forward traced items to the parent **Trace**. A **NoTrace** introduced in this hierarchy will cut off a branch from messaging to the root.

```

_unitHierarchy :: Assertion
_unitHierarchy = do
  cfg ← defaultConfigTesting
  msgs ← STM.newTVarIO []
  basetrace ← setupTrace $ TraceConfiguration cfg (MockSB msgs) "test" Neutral
  logInfo basetrace "This should have been displayed!"
  -- subtrace of trace which traces nothing
  setSubTrace cfg "test.inner" (Just NoTrace)
  trace1 ← appendName "inner" basetrace
  logInfo trace1 "This should NOT have been displayed!"
  setSubTrace cfg "test.inner.innermost" (Just Neutral)
  trace2 ← appendName "innermost" trace1
  logInfo trace2 "This should NOT have been displayed also due to the trace one level above"
  -- acquire the traced objects
  res ← STM.readTVarIO msgs
  -- only the first message should have been traced
  assertBool
    ("Found more or less messages than expected: " ++ show res)
    (length res == 1)

```

### Change a trace's minimum severity

A trace is configured with a minimum severity and filters out messages that are labelled with a lower severity. This minimum severity of the current trace can be changed.

```

_unitTraceMinSeverity :: Assertion
_unitTraceMinSeverity = do
  cfg ← defaultConfigTesting
  msgs ← STM.newTVarIO []
  trace ← setupTrace $ TraceConfiguration cfg (MockSB msgs) "test min severity" Neutral
  logInfo trace "Message #1"
  -- raise the minimum severity to Warning
  setMinSeverity cfg Warning
  msev ← Cardano.BM.Configuration.minSeverity cfg
  assertBool ("min severity should be Warning, but is " ++ (show msev))
    (msev == Warning)
  -- this message will not be traced
  logInfo trace "Message #2"
  -- lower the minimum severity to Info
  setMinSeverity cfg Info
  -- this message is traced
  logInfo trace "Message #3"
  -- acquire the traced objects
  res ← STM.readTVarIO msgs
  -- only the first and last messages should have been traced
  assertBool
    ("Found more or less messages than expected: " ++ show res)
    (length res == 2)

```

```

assertBool
  ("Found Info message when Warning was minimum severity: " ++ show res)
(all
  (λcase
    LogObject _ (LOMeta _ _ Info _) (LogMessage "Message #2") → False
    _ → True)
  res)

```

### Define a subtrace's behaviour to duplicate all messages

The **SubTrace** will duplicate all messages that pass through it. Each message will be in its own named context.

```

unitTraceDuplicate :: Assertion
unitTraceDuplicate = do
  cfg ← defaultConfigTesting
  msgs ← STM.newTVarIO []
  basetrace ← setupTrace $ TraceConfiguration cfg (MockSB msgs) "test-duplicate" Neutral
  logInfo basetrace "Message #1"
  -- create a subtrace which duplicates all messages
  setSubTrace cfg "test-duplicate.orig" $ Just (TeeTrace "test-duplicate.dup")
  trace ← appendName "orig" basetrace
  -- this message will be duplicated
  logInfo trace "You will see me twice!"
  -- acquire the traced objects
  res ← STM.readTVarIO msgs
  -- only the first and last messages should have been traced
  assertBool
    ("Found more or less messages than expected: " ++ show res)
    (length res == 3)

```

### Change the minimum severity of a named context

A trace of a named context can be configured with a minimum severity, such that the trace will filter out messages that are labelled with a lower severity.

```

unitNamedMinSeverity :: Assertion
unitNamedMinSeverity = do
  cfg ← defaultConfigTesting
  msgs ← STM.newTVarIO []
  basetrace ← setupTrace $ TraceConfiguration cfg (MockSB msgs) "test-named-severity" Neutral
  trace ← appendName "sev-change" basetrace
