

Cardano.BM - benchmarking and logging

Alexander Diemand

Andreas Triantafyllos

November 2018

Abstract

This is a framework that combines logging, benchmarking and monitoring. Complex evaluations of STM or monadic actions can be observed from outside while reading operating system counters before and after, and calculating their differences, thus relating resource usage to such actions. Through interactive configuration, the runtime behaviour of logging or the measurement of resource usage can be altered. Further reduction in logging can be achieved by redirecting log messages to an aggregation function which will output the running statistics with less frequency than the original message.

Chapter 1

Cardano BM

1.1 Overview

In figure 1.1 we display the relationships among modules in *Cardano.BM*. The arrows indicate import of a module. The arrows with a triangle at one end would signify "inheritance" in object-oriented programming, but we use it to show that one module replaces the other in the namespace, thus refines its interface.

1.2 Introduction

1.2.1 Logging with **Trace**

1.2.2 Setup procedure

Hierarchy of **Traces**

1.2.3 Measuring *Observables*

1.2.4 Information reduction in **Aggregation**

1.2.5 Output selection

1.2.6 Monitoring

1.3 Examples

1.3.1 Observing evaluation of a STM action

1.3.2 Observing evaluation of a monad action

1.3.3 Simple example showing plain logging

```
{-# LANGUAGE OverloadedStrings #-}
module Main
  (main)
  where
import Control.Concurrent (threadDelay)
import Cardano.BM.Configuration.Static (defaultConfigStdout)
```

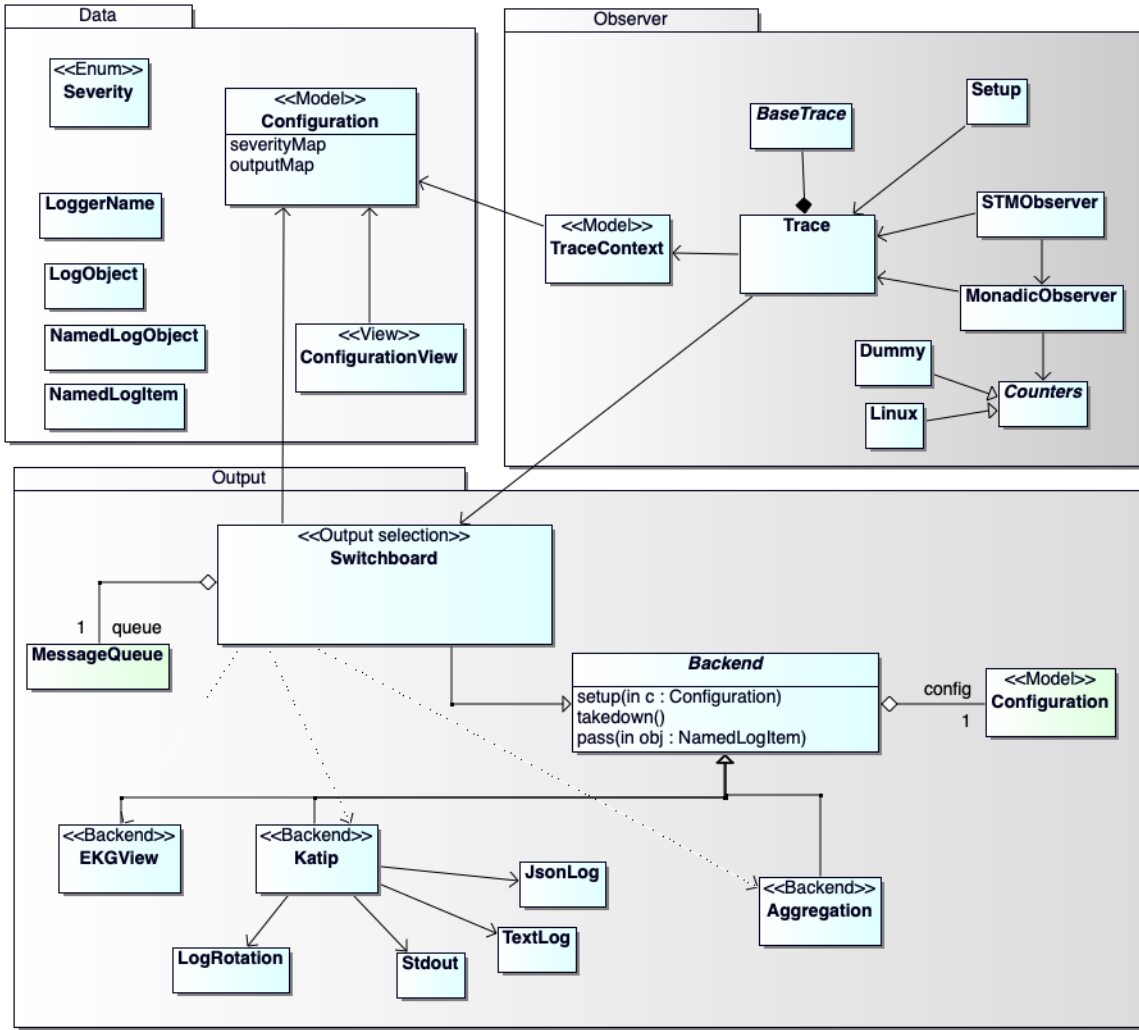

Figure 1.1: Overview of module relationships

```

import Cardano.BM.Setup (setupTrace)
import Cardano.BM.Trace (logDebug, logError, logInfo, logNotice,
                          logWarning)

main :: IO ()
main = do
  c ← defaultConfigStdout
  tr ← setupTrace (Right c) "simple"
  logDebug tr "this is a debug message"
  logInfo tr "this is an information."
  logNotice tr "this is a notice!"
  logWarning tr "this is a warning!"
  logError tr "this is an error!"
  threadDelay 80000

```

Figure 1.2: Setup procedure

```
return ()
```

1.3.4 Complex example showing logging, aggregation of log items, and observing IO actions

Module header and import directives

```

{-# LANGUAGE OverloadedStrings #-}
module Main
  (main)
  where
import Control.Concurrent (threadDelay)
import qualified Control.Concurrent.Async as Async
import Control.Monad (forM, forM_)
import GHC.Conc.Sync (STM, TVar, atomically, newTVar, readTVar, writeTVar)
import Data.Text (pack)
import System.Random

import qualified Cardano.BM.Configuration.Model as CM
import Cardano.BM.Data.Aggregated (Measurable (..))
import Cardano.BM.Data.AggregatedKind
import Cardano.BM.Data.BackendKind
import Cardano.BM.Data.LogItem
import Cardano.BM.Data.Observable
import Cardano.BM.Data.Output
import Cardano.BM.Data.Severity
import Cardano.BM.Data.SubTrace
import Cardano.BM.Observer.Monad (bracketObserveIO)
import qualified Cardano.BM.Observer.STM as STM
import Cardano.BM.Setup
import Cardano.BM.Trace
  
```

Define configuration

The output can be viewed in EKG on <http://localhost:12789>.

```

_ ← Async.waitCatch procRandom
return ()

```

1.4 Code listings

1.4.1 Cardano.BM.Observer.STM

```

stmWithLog :: STM.STM (t, [LogObject]) → STM.STM (t, [LogObject])
stmWithLog action = action

```

Observe STM action in a named context

With given name, create a **SubTrace** according to **Configuration** and run the passed STM action on it.

```

bracketObserveIO :: Trace IO → Text → STM.STM t → IO t
bracketObserveIO logTrace0 name action = do
  logTrace ← subTrace name logTrace0
  let subtrace = typeofTrace logTrace
  bracketObserveIO' subtrace logTrace action
where
  bracketObserveIO' :: SubTrace → Trace IO → STM.STM t → IO t
  bracketObserveIO' NoTrace _ act =
    STM.atomically act
  bracketObserveIO' subtrace logTrace act = do
    mCountersid ← observeOpen subtrace logTrace
    -- run action; if an exception is caught will be logged and rethrown.
    t ← (STM.atomically act) 'catch' (λ(e :: SomeException) → (logError logTrace (pack (show e)) >> throwM e))
    case mCountersid of
      Left openException →
        -- since observeOpen faced an exception there is no reason to call observeClose
        -- however the result of the action is returned
        logNotice logTrace ("ObserveOpen: " <> pack (show openException))
      Right countersid → do
        res ← observeClose subtrace logTrace countersid [ ]
        case res of
          Left ex → logNotice logTrace ("ObserveClose: " <> pack (show ex))
          _ → pure ()
    pure t

```

Observe STM action in a named context and output captured log items

The STM action might output messages, which after "success" will be forwarded to the logging trace. Otherwise, this function behaves the same as **Observe STM action in a named context**.

```

bracketObserveLogIO :: Trace IO → Text → STM.STM (t, [LogObject]) → IO t
bracketObserveLogIO logTrace0 name action = do
  logTrace ← subTrace name logTrace0
  let subtrace = typeofTrace logTrace
  bracketObserveLogIO' subtrace logTrace action
where
  bracketObserveLogIO' :: SubTrace → Trace IO → STM.STM (t, [LogObject]) → IO t
  bracketObserveLogIO' NoTrace _ act = do
    (t, _) ← STM.atomically $ stmWithLog act
    pure t
  bracketObserveLogIO' subtrace logTrace act = do
    mCountersid ← observeOpen subtrace logTrace
    -- run action, return result and log items; if an exception is
    -- caught will be logged and rethrown.
    (t, as) ← (STM.atomically $ stmWithLog act) 'catch'
      (λ(e :: SomeException) → (logError logTrace (pack (show e)) >> throwMe e))
    case mCountersid of
      Left openException →
        -- since observeOpen faced an exception there is no reason to call observeClose
        -- however the result of the action is returned
        logNotice logTrace ("ObserveOpen: " <> pack (show openException))
      Right countersid → do
        res ← observeClose subtrace logTrace countersid as
        case res of
          Left ex → logNotice logTrace ("ObserveClose: " <> pack (show ex))
          _ → pure ()
    pure t

```

1.4.2 Cardano.BM.Observer.Monad**Monadic.bracketObserverIO**

Observes an IO action and adds a name to the logger name of the passed in **Trace**. An empty **Text** leaves the logger name untouched.

Microbenchmarking steps:

1. Create a *trace* which will have been configured to observe things besides logging.

```

import qualified Cardano.BM.Configuration.Model as CM
○○○
c ← config
trace@(ctx, _) ← setupTrace (Right c) "demo-playground"

```

```

where
  config :: IO CM.Configuration
  config = do
    c ← CM.empty
    CM.setMinSeverity c Debug
    CM.setSetupBackends c [KatipBK, AggregationBK]
    CM.setDefaultBackends c [KatipBK, AggregationBK]
    CM.setSetupScribes c [ScribeDefinition {
      scName = "stdout"
      , scKind = StdoutSK
      , scRotation = Nothing
    }
    ]
    CM.setDefaultScribes c ["StdoutSK::stdout"]
  return c

```

2. *c* is the **Configuration** of *trace*. In order to enable the collection and processing of measurements (min, max, mean, std-dev) *AggregationBK* is needed.

```
CM.setDefaultBackends c [KatipBK, AggregationBK]
```

in a configuration file (YAML) means

```

defaultBackends:
- KatipBK
- AggregationBK

```

3. Set the measurements that you want to take by changing the configuration of the *trace* using *setSubTrace*, in order to declare the namespace where we want to enable the particular measurements and the list with the kind of measurements.

```

CM.setSubTrace
  (configuration ctx)
  "demo-playground.submit-tx"
  (Just $ ObservableTrace observablesSet)
where
  observablesSet = [MonotonicClock, MemoryStats]

```

4. Find an action to measure. e.g.:

```
runProtocolWithPipe x hdl proto 'catch' (λProtocolStopped → return ())
```

and use **bracketObserveIO**. e.g.:

```

bracketObserveIO trace "submit-tx" $
  runProtocolWithPipe x hdl proto 'catch' (λProtocolStopped → return ())

```

```

bracketObserveIO :: Trace IO → Text → IO t → IO t
bracketObserveIO logTrace0 name action = do

```

```

logTrace ← subTrace name logTrace0
bracketObserveIO' (typeofTrace logTrace) logTrace action
where
bracketObserveIO' :: SubTrace → Trace IO → IO t → IO t
bracketObserveIO' NoTrace _ act = act
bracketObserveIO' subtrace logTrace act = do
  mCountersid ← observeOpen subtrace logTrace
  -- run action; if an exception is caught will be logged and rethrown.
  t ← act 'catch' (λe :: SomeException) → (logError logTrace (pack (show e)) >> throwM e))
  case mCountersid of
    Left openException →
      -- since observeOpen faced an exception there is no reason to call observeClose
      -- however the result of the action is returned
      logNotice logTrace ("ObserveOpen: " <> pack (show openException))
    Right countersid → do
      res ← observeClose subtrace logTrace countersid [ ]
      case res of
        Left ex → logNotice logTrace ("ObserveClose: " <> pack (show ex))
        _ → pure ()
  pure t

```

Monadic.bracketObserverM

Observes a *MonadIO* $m \Rightarrow m$ action and adds a name to the logger name of the passed in **Trace**. An empty *Text* leaves the logger name untouched.

```

bracketObserveM :: (MonadCatch m, MonadIO m) ⇒ Trace IO → Text → m t → m t
bracketObserveM logTrace0 name action = do
  logTrace ← liftIO $ subTrace name logTrace0
  bracketObserveM' (typeofTrace logTrace) logTrace action
where
bracketObserveM' :: (MonadCatch m, MonadIO m) ⇒ SubTrace → Trace IO → m t → m t
bracketObserveM' NoTrace _ act = act
bracketObserveM' subtrace logTrace act = do
  mCountersid ← liftIO $ observeOpen subtrace logTrace
  -- run action; if an exception is caught will be logged and rethrown.
  t ← act 'catch'
    (λe :: SomeException) → (liftIO (logError logTrace (pack (show e)) >> throwM e)))
  case mCountersid of
    Left openException →
      -- since observeOpen faced an exception there is no reason to call observeClose
      -- however the result of the action is returned
      liftIO $ logNotice logTrace ("ObserveOpen: " <> pack (show openException))
    Right countersid → do
      res ← liftIO $ observeClose subtrace logTrace countersid [ ]
      case res of
        Left ex → liftIO (logNotice logTrace ("ObserveClose: " <> pack (show ex)))

```

```

    - → pure ()
  pure t

```

observerOpen

```

observeOpen :: SubTrace → Trace IO → IO (Either SomeException CounterState)
observeOpen subtrace logTrace = (do
  identifier ← newUnique
  -- take measurement
  counters ← readCounters subtrace
  let state = CounterState identifier counters
  if counters == []
  then return ()
  else do
    -- send opening message to Trace
    traceNamedObject logTrace <<
      LogObject <$> mkLOMeta <*> pure (ObserveOpen state)
    return (Right state)) 'catch' (return ∘ Left)

```

observeClose

```

observeClose :: SubTrace → Trace IO → CounterState → [LogObject] → IO (Either SomeException ())
observeClose subtrace logTrace initState logObjects = (do
  let identifier = csIdentifier initState
      initialCounters = csCounters initState
  -- take measurement
  counters ← readCounters subtrace
  if counters == []
  then return ()
  else do
    mle ← mkLOMeta
    -- send closing message to Trace
    traceNamedObject logTrace $
      LogObject mle (ObserveClose (CounterState identifier counters))
    -- send diff message to Trace
    traceNamedObject logTrace $
      LogObject mle (ObserveDiff (CounterState identifier (diffCounters initialCounters counters)))
    -- trace the messages gathered from inside the action
    forM_ logObjects $ traceNamedObject logTrace
    return (Right ())) 'catch' (return ∘ Left)

```

1.4.3 BaseTrace

Contravariant

A covariant is a functor: $F A \rightarrow F B$

A contravariant is a functor: $F B \rightarrow F A$

$Op\ a\ b$ implements the inverse to 'arrow' " $getOp :: b \rightarrow a$ ", which when applied to a **BaseTrace** of type " $Op\ (m\ ())\ s$ ", yields " $s \rightarrow m\ ()$ ". In our case, Op accepts an action in a monad m with input type **LogNamed LogObject** (see 'Trace').

```
newtype BaseTrace m s = BaseTrace {runTrace :: Op (m ()) s}
```

contramap

A covariant functor defines the function " $fmap :: (a \rightarrow b) \rightarrow f\ a \rightarrow f\ b$ ". In case of a contravariant functor, it is the dual function " $contramap :: (a \rightarrow b) \rightarrow f\ b \rightarrow f\ a$ " which is defined.

In the following instance, $runTrace$ extracts type " $Op\ (m\ ())\ s$ " to which $contramap$ applies f , thus " $f\ s \rightarrow m\ ()$ ". The constructor **BaseTrace** restores " $Op\ (m\ ())\ (f\ s)$ ".

```
instance Contravariant (BaseTrace m) where
  contramap f = BaseTrace . contramap f . runTrace
```

traceWith

Accepts a **Trace** and some payload s . First it gets the contravariant from the **Trace** as type " $Op\ (m\ ())\ s$ " and, after " $getOp :: b \rightarrow a$ " which translates to " $s \rightarrow m\ ()$ ", calls the action on the **LogNamed LogObject**.

```
traceWith :: BaseTrace m s -> s -> m ()
traceWith = getOp . runTrace
```

natTrace

Natural transformation from monad m to monad n .

```
natTrace :: (forall x . m x -> n x) -> BaseTrace m s -> BaseTrace n s
natTrace nat (BaseTrace (Op tr)) = BaseTrace $ Op $ nat . tr
```

noTrace

A **Trace** that discards all inputs.

```
noTrace :: Applicative m => BaseTrace m a
noTrace = BaseTrace $ Op $ const (pure ())
```

1.4.4 Cardano.BM.Trace

Utilities

Natural transformation from monad m to monad n .

```
natTrace :: (forall x . m x -> n x) -> Trace m -> Trace n
natTrace nat (ctx, trace) = (ctx, BaseTrace.natTrace nat trace)
```

Access type of **Trace**.

```
typeofTrace :: Trace m → SubTrace
typeofTrace (ctx, _) = tracetype ctx
```

Update type of **Trace**.

```
updateTracetype :: SubTrace → Trace m → Trace m
updateTracetype subtr (ctx, tr) = (ctx { tracetype = subtr }, tr)
```

Enter new named context

The context name is created and checked that its size is below a limit (currently 80 chars). The minimum severity that a log message must be labelled with is looked up in the configuration and recalculated.

```
appendName :: MonadIO m ⇒ LoggerName → Trace m → m (Trace m)
appendName name (ctx, trace) = do
  let prevLoggerName = loggerName ctx
      prevMinSeverity = minSeverity ctx
      newLoggerName = appendWithDot prevLoggerName name
      globMinSeverity ← liftIO $ Config.minSeverity (configuration ctx)
      namedSeverity ← liftIO $ Config.inspectSeverity (configuration ctx) newLoggerName
  case namedSeverity of
    Nothing → return (ctx { loggerName = newLoggerName }, trace)
    Just sev → return (ctx { loggerName = newLoggerName
                          , minSeverity = max (max sev prevMinSeverity) globMinSeverity }
                      , trace)

appendWithDot :: LoggerName → LoggerName → LoggerName
appendWithDot "" newName = T.take 80 newName
appendWithDot xs "" = xs
appendWithDot xs newName = T.take 80 $ xs <> " ." <> newName
```

Contramap a trace and produce the naming context

```
named :: BaseTrace.BaseTrace m (LogNamed i) → LoggerName → BaseTrace.BaseTrace m i
named trace name = contramap (LogNamed name) trace
```

Trace a **LogObject** through

```
traceNamedObject
  :: MonadIO m
  ⇒ Trace m
  → LogObject
  → m ()
traceNamedObject trace@(ctx, logTrace) lo@(LogObject _ lc) = do
```

```

let lname = loggerName ctx
doOutput ← case (typeofTrace trace) of
  FilterTrace filters →
    case lc of
      LogValue lname _ →
        return $ evalFilters filters (lname <> "." <> lname)
      _ →
        return $ evalFilters filters lname
  TeeTrace secName → do
    -- create a newly named copy of the LogObject
    BaseTrace.traceWith (named logTrace (lname <> "." <> secName)) lo
    return True
  _ → return True
if doOutput
then BaseTrace.traceWith (named logTrace lname) lo
else return ()

```

Evaluation of FilterTrace

A filter consists of a *DropName* and a list of *UnhideNames*. If the context name matches the *DropName* filter, then at least one of the *UnhideNames* must match the name to have the evaluation of the filters return *True*.

```

evalFilters :: [(DropName, UnhideNames)] → LoggerName → Bool
evalFilters fs nm =
  all (λ(no, yes) → if (dropFilter nm no) then (unhideFilter nm yes) else True) fs
where
  dropFilter :: LoggerName → DropName → Bool
  dropFilter name (Drop sel) = {-not -} (matchName name sel)
  unhideFilter :: LoggerName → UnhideNames → Bool
  unhideFilter _ (Unhide [ ]) = False
  unhideFilter name (Unhide us) = any (λsel → matchName name sel) us
  matchName :: LoggerName → NameSelector → Bool
  matchName name (Exact name') = name ≡ name'
  matchName name (StartsWith prefix) = T.isPrefixOf prefix name
  matchName name (EndsWith postfix) = T.isSuffixOf postfix name
  matchName name (Contains name') = T.isInfixOf name' name

```

Concrete Trace on stdout

This function returns a trace with an action of type "**(LogNamed LogObject) → IO ()**" which will output a text message as text and all others as JSON encoded representation to the console.

TODO remove locallock

```

locallock :: MVar ()
locallock = unsafePerformIO $ newMVar ()

```

```

stdoutTrace :: TraceNamed IO
stdoutTrace = BaseTrace.BaseTrace $ Op $ λ(LogNamed logname (LogObject _ lc)) →
  withMVar locallock $ \_ →
    case lc of
      (LogMessage logItem) →
        output logname $ liPayload logItem
      obj →
        output logname $ toStrict (encodeToLazyText obj)
  where
    output nm msg = TIO.putStrLn $ nm <> " :: " <> msg

```

Concrete Trace into a TVar

```

traceInTVar :: STM.TVar [a] → BaseTrace.BaseTrace STM.STM a
traceInTVar tvar = BaseTrace.BaseTrace $ Op $ λa → STM.modifyTVar tvar ((:) a)
traceInTVarIO :: STM.TVar [LogObject] → TraceNamed IO
traceInTVarIO tvar = BaseTrace.BaseTrace $ Op $ λln →
  STM.atomically $ STM.modifyTVar tvar ((:) (lnItem ln))
traceNamedInTVarIO :: STM.TVar [LogNamed LogObject] → TraceNamed IO
traceNamedInTVarIO tvar = BaseTrace.BaseTrace $ Op $ λln →
  STM.atomically $ STM.modifyTVar tvar ((:) ln)

```

Check a log item's severity against the **Trace**'s minimum severity

do we need three different **minSeverity** defined?

We do a lookup of the global **minSeverity** in the configuration. And, a lookup of the **minSeverity** for the current named context. These values might have changed in the meanwhile. A third filter is the **minSeverity** defined in the current context.

```

traceConditionally
  :: MonadIO m
  ⇒ Trace m
  → LogObject
  → m ()
traceConditionally logTrace@(ctx, _) msg@(LogObject _ (LogMessage item)) = do
  globminsev ← liftIO $ Config.minSeverity (configuration ctx)
  globnamesev ← liftIO $ Config.inspectSeverity (configuration ctx) (loggerName ctx)
  let minsev = max (minSeverity ctx) $ max globminsev (fromMaybe Debug globnamesev)
  flag = (liSeverity item) ≥ minsev
  when flag $ traceNamedObject logTrace msg
traceConditionally logTrace logObject =
  traceNamedObject logTrace logObject

```

Enter message into a trace

The function `traceNamedItem` creates a `LogObject` and threads this through the action defined in the `Trace`.

```

traceNamedItem
  :: MonadIO m
  ⇒ Trace m
  → LogSelection
  → Severity
  → T.Text
  → m ()
traceNamedItem trace p s m =
  traceConditionally trace ≪≪
    LogObject < $ > liftIO mkLOMeta
      < * > pure (LogMessage LogItem {liSelection = p
        , liSeverity = s
        , liPayload = m
        })

```

Logging functions

```

logDebug, logInfo, logNotice, logWarning, logError, logCritical, logAlert, logEmergency
  :: MonadIO m ⇒ Trace m → T.Text → m ()
logDebug   logTrace = traceNamedItem logTrace Both Debug
logInfo    logTrace = traceNamedItem logTrace Both Info
logNotice  logTrace = traceNamedItem logTrace Both Notice
logWarning logTrace = traceNamedItem logTrace Both Warning
logError   logTrace = traceNamedItem logTrace Both Error
logCritical logTrace = traceNamedItem logTrace Both Critical
logAlert   logTrace = traceNamedItem logTrace Both Alert
logEmergency logTrace = traceNamedItem logTrace Both Emergency

logDebugS, logInfoS, logNoticeS, logWarningS, logErrorS, logCriticalS, logAlertS, logEmergencyS
  :: MonadIO m ⇒ Trace m → T.Text → m ()
logDebugS   logTrace = traceNamedItem logTrace Private Debug
logInfoS    logTrace = traceNamedItem logTrace Private Info
logNoticeS  logTrace = traceNamedItem logTrace Private Notice
logWarningS logTrace = traceNamedItem logTrace Private Warning
logErrorS   logTrace = traceNamedItem logTrace Private Error
logCriticalS logTrace = traceNamedItem logTrace Private Critical
logAlertS   logTrace = traceNamedItem logTrace Private Alert
logEmergencyS logTrace = traceNamedItem logTrace Private Emergency

logDebugP, logInfoP, logNoticeP, logWarningP, logErrorP, logCriticalP, logAlertP, logEmergencyP
  :: MonadIO m ⇒ Trace m → T.Text → m ()
logDebugP   logTrace = traceNamedItem logTrace Public Debug
logInfoP    logTrace = traceNamedItem logTrace Public Info
logNoticeP  logTrace = traceNamedItem logTrace Public Notice

```

```

      tr' <- appendName name tr
      return $ updateTracetype subtrace tr'
    NoTrace      -> return $ updateTracetype subtrace (ctx, BaseTrace.BaseTrace $ Op $ \_ -> pure ())
    DropOpening  -> return $ updateTracetype subtrace (ctx, BaseTrace.BaseTrace $ Op $
      \ (LogNamed _ lo@(LogObject _ lc)) -> do
        case lc of
          ObserveOpen _ -> return ()
          _ -> traceNamedObject tr lo)

```

```

ObservableTrace _ → do
  tr' ← appendName name tr
  return $ updateTracetype subtrace tr'

```

1.4.5 Cardano.BM.Setup

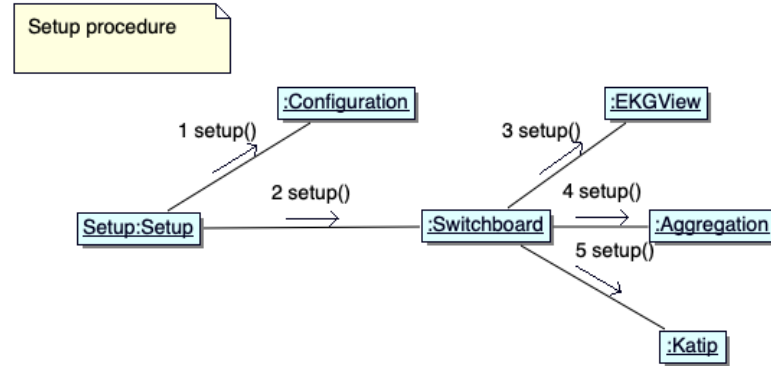

Figure 1.3: Setup procedure

setupTrace

Setup a new **Trace** (**Trace**) with either a given **Configuration** (**Configuration.Model**) or a **FilePath** to a configuration file. After all tracing operations have ended; *shutdownTrace* must be called.

```

setupTrace :: MonadIO m ⇒ Either FilePath Config.Configuration → Text → m (Trace m)
setupTrace (Left cfgFile) name = do
  c ← liftIO $ Config.setup cfgFile
  setupTrace_ c name
setupTrace (Right c) name = setupTrace_ c name
setupTrace_ :: MonadIO m ⇒ Config.Configuration → Text → m (Trace m)
setupTrace_ c name = do
  sb ← liftIO $ Switchboard.realize c
  sev ← liftIO $ Config.minSeverity c
  ctx ← liftIO $ newContext "" c sev sb
  subTrace name $ natTrace liftIO (ctx, Switchboard.mainTrace sb)

```

shutdownTrace

Shut down a Trace and all the **Traces** related to it.

```

shutdownTrace :: MonadIO m ⇒ Trace m → m ()
shutdownTrace (ctx, _) = liftIO $ shutdown ctx

```

withTrace

```

withTrace :: (MonadIO m, MonadMask m) => Config.Configuration -> Text -> (Trace m -> m t) -> m t
withTrace cfg name action =
    bracket (setupTrace (Right cfg) name) shutdownTrace action

```

newContext

```

newContext :: LoggerName
    -> Config.Configuration
    -> Severity
    -> Switchboard.Switchboard
    -> IO TraceContext
newContext name cfg sev sb = do
    return $ TraceContext {
        loggerName = name
        , configuration = cfg
        , minSeverity = sev
        , tracetype = Neutral
        , shutdown = unrealize sb
    }

```

1.4.6 Cardano.BM.Counters

Here the platform is chosen on which we compile this program.

Currently, we mainly support *Linux* with its 'proc' filesystem.

```

{-# LANGUAGE CPP #-}
# if defined (linux_HOST_OS)
# define LINUX
# endif
module Cardano.BM.Counters
(
    Platform.readCounters
    , diffTimeObserved
    , getMonoClock
) where
# ifdef LINUX
import qualified Cardano.BM.Counters.Linux as Platform
# else
import qualified Cardano.BM.Counters.Dummy as Platform
# endif
import Cardano.BM.Counters.Common (getMonoClock)
import Cardano.BM.Data.Aggregated (Measurable (..))
import Cardano.BM.Data.Counter

```

Calculate difference between clocks

```

diffTimeObserved :: CounterState → CounterState → Measurable
diffTimeObserved (CounterState id0 startCounters) (CounterState id1 endCounters) =
  let
    startTime = getMonotonicTime startCounters
    endTime = getMonotonicTime endCounters
  in
    if (id0 == id1)
    then endTime - startTime
    else error "these clocks are not from the same experiment"
where
  getMonotonicTime counters = case (filter isMonotonicClockCounter counters) of
    [(Counter MonotonicClockTime _ mus)] → mus
    _ → error "A time measurement is missing!"
  isMonotonicClockCounter :: Counter → Bool
  isMonotonicClockCounter = (MonotonicClockTime ==) ∘ cType

```

1.4.7 Cardano.BM.Counters.Common

Common functions that serve *readCounters* on all platforms.

```

nominalTimeToMicroseconds :: Word64 → Microsecond
nominalTimeToMicroseconds = fromMicroseconds ∘ toInteger ∘ ('div' 1000)

```

Read monotonic clock

```

getMonoClock :: IO [Counter]
getMonoClock = do
  t ← getMonotonicTimeNSec
  return [Counter MonotonicClockTime "monoclock" $ Microseconds (t `div` 1000)]

```

Read GHC RTS statistics

Read counters from GHC's RTS (runtime system). The values returned are as per the last GC (garbage collection) run.

```

readRTSStats :: IO [Counter]
readRTSStats = do
  iscollected ← GhcStats.getRTSStatsEnabled
  if iscollected
  then ghcstats
  else return []
where
  ghcstats :: IO [Counter]
  ghcstats = do

```

```

-- need to run GC?
rts ← GhcStats.getRTSStats
let getrts = ghcvall rts
return [getrts (Bytes ∘ fromIntegral ∘ GhcStats.allocated_bytes, "bytesAllocated")
      ,getrts (Bytes ∘ fromIntegral ∘ GhcStats.max_live_bytes, "liveBytes")
      ,getrts (Bytes ∘ fromIntegral ∘ GhcStats.max_large_objects_bytes, "largeBytes")
      ,getrts (Bytes ∘ fromIntegral ∘ GhcStats.max_compact_bytes, "compactBytes")
      ,getrts (Bytes ∘ fromIntegral ∘ GhcStats.max_slop_bytes, "slopBytes")
      ,getrts (Bytes ∘ fromIntegral ∘ GhcStats.max_mem_in_use_bytes, "usedMemBytes")
      ,getrts (Nanoseconds ∘ fromIntegral ∘ GhcStats.gc_cpu_ns, "gcCpuNs")
      ,getrts (Nanoseconds ∘ fromIntegral ∘ GhcStats.gc_elapsed_ns, "gcElapsedNs")
      ,getrts (Nanoseconds ∘ fromIntegral ∘ GhcStats.cpu_ns, "cpuNs")
      ,getrts (Nanoseconds ∘ fromIntegral ∘ GhcStats.elapsed_ns, "elapsedNs")
      ,getrts (PureI ∘ toInteger ∘ GhcStats.gcs, "gcNum")
      ,getrts (PureI ∘ toInteger ∘ GhcStats.major_gcs, "gcMajorNum")
      ]
ghcvall :: GhcStats.RTSStats → ((GhcStats.RTSStats → Measurable), Text) → Counter
ghcvall s (f,n) = Counter RTSStats n $ (f s)

```

1.4.8 Cardano.BM.Counters.Dummy

This is a dummy definition of `readCounters` on platforms that do not support the 'proc' filesystem from which we would read the counters.

The only supported measurements are monotonic clock time and RTS statistics for now.

```

readCounters :: SubTrace → IO [Counter]
readCounters NoTrace      = return []
readCounters Neutral      = return []
readCounters (TeeTrace _) = return []
readCounters (FilterTrace _) = return []
readCounters UntimedTrace = return []
readCounters DropOpening  = return []
readCounters (ObservableTrace tts) = foldrM (λ(sel,fun) a →
  if any (≡ sel) tts
  then (fun ≫ λxs → return $ a ++ xs)
  else return a) [] selectors
where
  selectors = [(MonotonicClock, getMonoClock)
    -- , (MemoryStats, readProcStatM)
    -- , (ProcessStats, readProcStats)
    -- , (IOStats, readProcIO)
    , (GhcRtsStats, readRTSStats)
    ]

```

1.4.9 Cardano.BM.Counters.Linux

we have to expand the `readMemStats` function to read full data from `proc`

```

readCounters :: SubTrace → IO [Counter]
readCounters NoTrace      = return [ ]
readCounters Neutral      = return [ ]
readCounters (TeeTrace _) = return [ ]
readCounters (FilterTrace _) = return [ ]
readCounters UntimedTrace = return [ ]
readCounters DropOpening  = return [ ]
readCounters (ObservableTrace tts) = foldrM (λ(sel,fun) a →
  if any (≡ sel) tts
  then (fun >> λxs → return $ a ++ xs)
  else return a) [ ] selectors
where
  selectors = [ (MonotonicClock, getMonoClock)
    , (MemoryStats, readProcStatM)
    , (ProcessStats, readProcStats)
    , (IOStats, readProcIO)
    ]

```

```

pathProc :: FilePath
pathProc = "/proc/"
pathProcStat :: ProcessID → FilePath
pathProcStat pid = pathProc </> (show pid) </> "stat"
pathProcStatM :: ProcessID → FilePath
pathProcStatM pid = pathProc </> (show pid) </> "statm"
pathProcIO :: ProcessID → FilePath
pathProcIO pid = pathProc </> (show pid) </> "io"

```

Reading from a file in /proc/<pid>

```

readProcList :: FilePath → IO [Integer]
readProcList fp = do
  cs ← readFile fp
  return $ map (λs → maybe 0 id $ (readMaybe s :: Maybe Integer)) (words cs)

```

readProcStatM - /proc/<pid>/statm

```

/proc/[pid]/statm
  Provides information about memory usage, measured in pages. The columns are:
    size      (1) total program size
               (same as VmSize in /proc/[pid]/status)
    resident  (2) resident set size
               (same as VmRSS in /proc/[pid]/status)
    shared    (3) number of resident shared pages (i.e., backed by a file)
               (same as RssFile+RssShmem in /proc/[pid]/status)
    text      (4) text (code)
    lib       (5) library (unused since Linux 2.6; always 0)
    data      (6) data + stack
    dt        (7) dirty pages (unused since Linux 2.6; always 0)

```

```

readProcStatM :: IO [Counter]
readProcStatM = do
    pid ← getProcessID
    ps0 ← readProcList (pathProcStatM pid)
    let ps = zip colnames ps0
        psUseful = filter (("unused" ≠) ∘ fst) ps
    return $ map (λ(n,i) → Counter MemoryCounter n (PureI i)) psUseful
where
    colnames :: [Text]
    colnames = ["size", "resident", "shared", "text", "unused", "data", "unused"]

```

readProcStats - //proc//<pid >//stat

/proc/[pid]/stat

Status information about the process. This is used by ps(1). It is defined in the kernel source file fs/proc/array.c.

The fields, in order, with their proper scanf(3) format specifiers, are listed below. Whether or not certain of these fields display valid information is governed by a ptrace access mode PTRACE_MODE_READ_FSCREDS | PTRACE_MODE_NOAUDIT check (refer to ptrace(2)). If the check denies access, then the field value is displayed as 0. The affected fields are indicated with the marking [PT].

- (1) pid %d
The process ID.
- (2) comm %s
The filename of the executable, in parentheses. This is visible whether or not the executable is swapped out.
- (3) state %c
One of the following characters, indicating process state:
 - R Running
 - S Sleeping in an interruptible wait
 - D Waiting in uninterruptible disk sleep
 - Z Zombie
 - T Stopped (on a signal) or (before Linux 2.6.33) trace stopped
 - t Tracing stop (Linux 2.6.33 onward)
 - W Paging (only before Linux 2.6.0)
 - X Dead (from Linux 2.6.0 onward)
 - x Dead (Linux 2.6.33 to 3.13 only)
 - K Wakekill (Linux 2.6.33 to 3.13 only)
 - W Waking (Linux 2.6.33 to 3.13 only)
 - P Parked (Linux 3.9 to 3.13 only)
- (4) ppid %d
The PID of the parent of this process.
- (5) pgrp %d
The process group ID of the process.

- (6) session %d
The session ID of the process.
- (7) tty_nr %d
The controlling terminal of the process. (The minor device number is contained in the combination of bits 31 to 20 and 7 to 0; the major device number is in bits 15 to 8.)
- (8) tpgid %d
The ID of the foreground process group of the controlling terminal of the process.
- (9) flags %u
The kernel flags word of the process. For bit meanings, see the PF_* defines in the Linux kernel source file include/linux/sched.h. Details depend on the kernel version.

The format for this field was %lu before Linux 2.6.
- (10) minflt %lu
The number of minor faults the process has made which have not required loading a memory page from disk.
- (11) cminflt %lu
The number of minor faults that the process's waited-for children have made.
- (12) majflt %lu
The number of major faults the process has made which have required loading a memory page from disk.
- (13) cmajflt %lu
The number of major faults that the process's waited-for children have made.
- (14) utime %lu
Amount of time that this process has been scheduled in user mode, measured in clock ticks (divide by sysconf(_SC_CLK_TCK)). This includes guest time, guest_time (time spent running a virtual CPU, see below), so that applications that are not aware of the guest time field do not lose that time from their calculations.
- (15) stime %lu
Amount of time that this process has been scheduled in kernel mode, measured in clock ticks (divide by sysconf(_SC_CLK_TCK)).
- (16) cutime %ld
Amount of time that this process's waited-for children have been scheduled in user mode, measured in clock ticks (divide by sysconf(_SC_CLK_TCK)). (See also times(2).) This includes guest time, cguest_time (time spent running a virtual CPU, see below).
- (17) cstime %ld
Amount of time that this process's waited-for children have been scheduled in kernel mode, measured in clock ticks (divide by sysconf(_SC_CLK_TCK)).
- (18) priority %ld
(Explanation for Linux 2.6) For processes running a real-time scheduling policy (policy below; see sched_setscheduler(2)), this is the negated scheduling priority, minus one; that is, a number in the range -2 to -100, corresponding to real-time priorities 1 to 99. For processes running under a non-real-time scheduling policy, this is the raw nice value (setpriority(2)) as represented in the kernel. The kernel stores nice values as numbers in the range 0 (high) to 39 (low), corresponding to the user-visible nice range of -20 to 19.
- (19) nice %ld
The nice value (see setpriority(2)), a value in the range 19 (low priority) to -20 (high priority).
- (20) num_threads %ld
Number of threads in this process (since Linux 2.6). Before kernel 2.6, this field was hard coded to 0 as a placeholder for an earlier removed field.
- (21) itrealvalue %ld
The time in jiffies before the next SIGALRM is sent to the process due to an interval timer. Since kernel 2.6.17, this field is no longer maintained, and is hard coded as 0.

- (22) starttime %llu
The time the process started after system boot. In kernels before Linux 2.6, this value was expressed in jiffies. Since Linux 2.6, the value is expressed in clock ticks (divide by `sysconf(_SC_CLK_TCK)`).

The format for this field was %lu before Linux 2.6.
- (23) vsize %lu
Virtual memory size in bytes.
- (24) rss %ld
Resident Set Size: number of pages the process has in real memory. This is just the pages which count toward text, data, or stack space. This does not include pages which have not been demand-loaded in, or which are swapped out.
- (25) rsslim %lu
Current soft limit in bytes on the rss of the process; see the description of RLIMIT_RSS in `getrlimit(2)`.
- (26) startcode %lu [PT]
The address above which program text can run.
- (27) endcode %lu [PT]
The address below which program text can run.
- (28) startstack %lu [PT]
The address of the start (i.e., bottom) of the stack.
- (29) kstkesp %lu [PT]
The current value of ESP (stack pointer), as found in the kernel stack page for the process.
- (30) kstkeip %lu [PT]
The current EIP (instruction pointer).
- (31) signal %lu
The bitmap of pending signals, displayed as a decimal number. Obsolete, because it does not provide information on real-time signals; use `/proc/[pid]/status` instead.
- (32) blocked %lu
The bitmap of blocked signals, displayed as a decimal number. Obsolete, because it does not provide information on real-time signals; use `/proc/[pid]/status` instead.
- (33) sigignore %lu
The bitmap of ignored signals, displayed as a decimal number. Obsolete, because it does not provide information on real-time signals; use `/proc/[pid]/status` instead.
- (34) sigcatch %lu
The bitmap of caught signals, displayed as a decimal number. Obsolete, because it does not provide information on real-time signals; use `/proc/[pid]/status` instead.
- (35) wchan %lu [PT]
This is the "channel" in which the process is waiting. It is the address of a location in the kernel where the process is sleeping. The corresponding symbolic name can be found in `/proc/[pid]/wchan`.
- (36) nswap %lu
Number of pages swapped (not maintained).
- (37) cnsnap %lu
Cumulative nswap for child processes (not maintained).
- (38) exit_signal %d (since Linux 2.1.22)
Signal to be sent to parent when we die.
- (39) processor %d (since Linux 2.2.8)
CPU number last executed on.

- (40) `rt_priority %u` (since Linux 2.5.19)
Real-time scheduling priority, a number in the range 1 to 99 for processes scheduled under a real-time policy, or 0, for non-real-time processes (see `sched_setscheduler(2)`).
- (41) `policy %u` (since Linux 2.5.19)
Scheduling policy (see `sched_setscheduler(2)`). Decode using the `SCHED_*` constants in `linux/sched.h`.

The format for this field was `%lu` before Linux 2.6.22.
- (42) `delayacct_blkio_ticks %llu` (since Linux 2.6.18)
Aggregated block I/O delays, measured in clock ticks (centiseconds).
- (43) `guest_time %lu` (since Linux 2.6.24)
Guest time of the process (time spent running a virtual CPU for a guest operating system), measured in clock ticks (divide by `sysconf(_SC_CLK_TCK)`).
- (44) `cguest_time %ld` (since Linux 2.6.24)
Guest time of the process's children, measured in clock ticks (divide by `sysconf(_SC_CLK_TCK)`).
- (45) `start_data %lu` (since Linux 3.3) [PT]
Address above which program initialized and uninitialized (BSS) data are placed.
- (46) `end_data %lu` (since Linux 3.3) [PT]
Address below which program initialized and uninitialized (BSS) data are placed.
- (47) `start_brk %lu` (since Linux 3.3) [PT]
Address above which program heap can be expanded with `brk(2)`.
- (48) `arg_start %lu` (since Linux 3.5) [PT]
Address above which program command-line arguments (`argv`) are placed.
- (49) `arg_end %lu` (since Linux 3.5) [PT]
Address below program command-line arguments (`argv`) are placed.
- (50) `env_start %lu` (since Linux 3.5) [PT]
Address above which program environment is placed.
- (51) `env_end %lu` (since Linux 3.5) [PT]
Address below which program environment is placed.
- (52) `exit_code %d` (since Linux 3.5) [PT]
The thread's exit status in the form reported by `waitpid(2)`.

readProcStats :: IO [Counter]

readProcStats = do

pid ← getProcessID

ps0 ← readProcList (pathProcStat pid)

psUseful = filter (("unused"* \neq) \circ fst) ps*

*return \$ map ($\lambda(n,i) \rightarrow$ Counter StatInfo *n* (PureI *i*)) psUseful*

where

colnames :: [Text]

colnames = ["pid", "unused", "unused", "ppid", "pgrp", "session", "ttynr", "tpgid", "flags", "minflt", "cmminflt", "majflt", "cmajflt", "utime", "stime", "cutime", "cstime", "priority", "nice", "num", "itrealvalue", "starttime", "vsize", "rss", "rsslim", "startcode", "endcode", "startstack", "signal", "blocked", "sigignore", "sigcatch", "wchan", "nswap", "cnsnap", "exitsignal", "proc", "policy", "blkio", "guesttime", "cguesttime", "startdata", "enddata", "startbrk", "argstart", "envend", "exitcode"
]

readProcIO - //proc//<pid >//io

/proc/[pid]/io (since kernel 2.6.20)

This file contains I/O statistics for the process, for example:

```
# cat /proc/3828/io
rchar: 323934931
wchar: 323929600
syscr: 632687
syscw: 632675
read_bytes: 0
write_bytes: 323932160
cancelled_write_bytes: 0
```

The fields are as follows:

rchar: characters read

The number of bytes which this task has caused to be read from storage. This is simply the sum of bytes which this process passed to read(2) and similar system calls. It includes things such as terminal I/O and is unaffected by whether or not actual physical disk I/O was required (the read might have been satisfied from pagecache).

wchar: characters written

The number of bytes which this task has caused, or shall cause to be written to disk. Similar caveats apply here as with rchar.

syscr: read syscalls

Attempt to count the number of read I/O operations—that is, system calls such as read(2) and pread(2).

syscw: write syscalls

Attempt to count the number of write I/O operations—that is, system calls such as write(2) and pwrite(2).

read_bytes: bytes read

Attempt to count the number of bytes which this process really did cause to be fetched from the storage layer. This is accurate for block-backed filesystems.

write_bytes: bytes written

Attempt to count the number of bytes which this process caused to be sent to the storage layer.

cancelled_write_bytes:

The big inaccuracy here is truncate. If a process writes 1MB to a file and then deletes the file, it will in fact perform no writeout. But it will have been accounted as having caused 1MB of write. In other words: this field represents the number of bytes which this process caused to not happen, by truncating pagecache. A task can cause "negative" I/O too. If this task truncates some dirty pagecache, some I/O which another task has been accounted for (in its write_bytes) will not be happening.

Note: In the current implementation, things are a bit racy on 32-bit systems: if process A reads process B's /proc/[pid]/io while process B is updating one of these 64-bit counters, process A could see an intermediate result.

Permission to access this file is governed by a ptrace access mode PTRACE_MODE_READ_FSCREDS check; see ptrace(2).

readProcIO :: IO [Counter]

readProcIO = do

pid ← getProcessID

ps0 ← readProcList (pathProcIO pid)

let ps = zip3 colnames ps0 units

return \$ map (λ(n,i,u) → Counter IOCounter n (u i)) ps

where

colnames :: [Text]

```
colnames = [ "rchar", "wchar", "syscr", "syscw", "rbytes", "wbytes", "cxwbytes" ]
units = [ Bytes ◦ fromInteger, Bytes ◦ fromInteger, PureI, PureI, Bytes ◦ fromInteger, Bytes ◦ fromInteger, Bytes ◦ fromInteger, Bytes ◦ fromInteger ]
```

1.4.10 Cardano.BM.Data.Aggregated

Measurable

A **Measurable** may consist of different types of values. Time measurements are strict, so are *Bytes* which are externally measured. The real or integral numeric values are lazily linked, so we can decide later to drop them.

```
data Measurable = Microseconds {-# UNPACK #-} ! Word64
  | Nanoseconds {-# UNPACK #-} ! Word64
  | Seconds      {-# UNPACK #-} ! Word64
  | Bytes        {-# UNPACK #-} ! Word64
  | PureD        Double
  | PureI        Integer
  deriving (Eq, Ord, Generic, ToJSON)
```

Measurable can be transformed to an integral value.

```
getInteger :: Measurable → Integer
getInteger (Microseconds a) = toInteger a
getInteger (Nanoseconds a) = toInteger a
getInteger (Seconds a)     = toInteger a
getInteger (Bytes a)       = toInteger a
getInteger (PureI a)       = a
getInteger (PureD a)       = round a
```

Measurable can be transformed to a rational value.

```
getDouble :: Measurable → Double
getDouble (Microseconds a) = fromIntegral a
getDouble (Nanoseconds a) = fromIntegral a
getDouble (Seconds a)     = fromIntegral a
getDouble (Bytes a)       = fromIntegral a
getDouble (PureI a)       = fromInteger a
getDouble (PureD a)       = a
```

It is a numerical value, thus supports functions to operate on numbers.

```
instance Num Measurable where
  (+) (Microseconds a) (Microseconds b) = Microseconds (a + b)
  (+) (Nanoseconds a) (Nanoseconds b) = Nanoseconds (a + b)
  (+) (Seconds a) (Seconds b) = Seconds (a + b)
  (+) (Bytes a) (Bytes b) = Bytes (a + b)
  (+) (PureI a) (PureI b) = PureI (a + b)
  (+) (PureD a) (PureD b) = PureD (a + b)
  (+) _ _ = error "Trying to add values with different units"
```

```

(*) (Microseconds a) (Microseconds b) = Microseconds (a * b)
(*) (Nanoseconds a) (Nanoseconds b) = Nanoseconds (a * b)
(*) (Seconds a)      (Seconds b)      = Seconds      (a * b)
(*) (Bytes a)        (Bytes b)        = Bytes        (a * b)
(*) (PureI a)        (PureI b)        = PureI        (a * b)
(*) (PureD a)        (PureD b)        = PureD        (a * b)
(*) -- -- -- -- -- = error "Trying to multiply values with different units"

    ", std-dev=" ++ show (stdevOfStats s) ++
    ", count=" ++ show (fcount s) ++
    " }"

```

Exponentially Weighted Moving Average (EWMA)

Following https://en.wikipedia.org/wiki/Moving_average#Exponential_moving_average we calculate the exponential moving average for a series of values Y_t according to:

$$S_t = \begin{cases} Y_1, & t = 1 \\ \alpha \cdot Y_t + (1 - \alpha) \cdot S_{t-1}, & t > 1 \end{cases}$$

```

data EWMA = EmptyEWMA {alpha :: Double}
    | EWMA {alpha :: Double
    , avg :: Measurable
    } deriving (Show, Eq, Generic, ToJSON)

```

Aggregated

```
data Aggregated = AggregatedStats Stats
  | AggregatedEWMA EWMA
  deriving (Eq, Generic, ToJSON)
```

instance Semigroup Aggregated disabled for the moment, because not needed.

```
instance Semigroup Aggregated where
  (<>) (AggregatedStats a) (AggregatedStats b) =
    AggregatedStats (a <> b)
  (<>) _ _ = error "Cannot combine different objects"
```

```
singletonStats :: Measurable → Aggregated
```

```
singletonStats a =
  let stats = Stats {flast = a
    ,fold          = 0
    ,fbasic = BaseStats
      {fmin = a
      ,fmax = a
      ,fcount = 1
      ,fsum_A = getDouble a
      ,fsum_B = 0}
    ,fdelta = BaseStats
      {fmin = 0
      ,fmax = 0
      ,fcount = 0

  show (AggregatedStats astats) =
    "{ stats = " ++ show astats ++ " }"
  show (AggregatedEWMA a) = show a
```

1.4.11 Cardano.BM.Data.Backend

Accepts a **NamedLogItem**

Instances of this type class accept a **NamedLogItem** and deal with it.

```
class IsEffectuator t where
  effectuate :: t → NamedLogItem → IO ()
  effectuatefrom :: forall s ◦ (IsEffectuator s) ⇒ t → NamedLogItem → s → IO ()
  default effectuatefrom :: forall s ◦ (IsEffectuator s) ⇒ t → NamedLogItem → s → IO ()
  effectuatefrom t nli _ = effectuate t nli
```

Declaration of a **Backend**

A backend is life-cycle managed, thus can be *realized* and *unrealized*.

```
class (IsEffectuator t) ⇒ IsBackend t where
  typeof    :: t → BackendKind
  realize    :: Configuration → IO t
  realizefrom :: forall s ◦ (IsEffectuator s) ⇒ Trace IO → s → IO t
  default realizefrom :: forall s ◦ (IsEffectuator s) ⇒ Trace IO → s → IO t
  realizefrom (ctx, _) _ = realize (configuration ctx)
  unrealize :: t → IO ()
```

Backend

This data structure for a backend defines its behaviour as an **IsEffectuator** when processing an incoming message, and as an **IsBackend** for unrealizing the backend.

```
data Backend = MkBackend
  { bEffectuate :: NamedLogItem → IO ()
  , bUnrealize :: IO ()
  }
```

1.4.12 Cardano.BM.Data.Configuration

Data structure to help parsing configuration files.

Representation

```
type Port = Int
data Representation = Representation
  { minSeverity    :: Severity
  , rotation       :: RotationParameters
  , setupScribes   :: [ScribeDefinition]
  , defaultScribes :: [(ScribeKind, Text)]
  , setupBackends  :: [BackendKind]
  , defaultBackends :: [BackendKind]
```

```

,hasEKG      :: Maybe Port
,hasGUI      :: Maybe Port
,options     :: HM.HashMap Text Object
}
deriving (Generic, Show, ToJSON, FromJSON)

```

parseRepresentation

```

parseRepresentation :: FilePath → IO Representation
parseRepresentation fp = do
  repr :: Representation ← decodeFileThrow fp
  return $ implicit_fill_representation repr

```

after parsing the configuration representation we implicitly correct it.

```

implicit_fill_representation :: Representation → Representation
implicit_fill_representation =
  remove_ekgview_if_not_defined ∘
  filter_duplicates_from_backends ∘
  filter_duplicates_from_scribes ∘
  union_setup_and_usage_backends ∘
  add_ekgview_if_port_defined ∘
  add_katip_if_any_scribes
where
  filter_duplicates_from_backends r =
    r { setupBackends = mkUniq $ setupBackends r }
  filter_duplicates_from_scribes r =
    r { setupScribes = mkUniq $ setupScribes r }
  union_setup_and_usage_backends r =
    r { setupBackends = setupBackends r <> defaultBackends r }
  remove_ekgview_if_not_defined r =
    case hasEKG r of
      Nothing → r { defaultBackends = filter (λbk → bk ≠ EKGViewBK) (defaultBackends r)
                  , setupBackends = filter (λbk → bk ≠ EKGViewBK) (setupBackends r)
                  }
      Just _ → r
  add_ekgview_if_port_defined r =
    case hasEKG r of
      Nothing → r
      Just _ → r { setupBackends = setupBackends r <> [EKGViewBK] }
  add_katip_if_any_scribes r =
    if (any ¬ [null $ setupScribes r, null $ defaultScribes r])
    then r { setupBackends = setupBackends r <> [KatipBK] }
    else r
  mkUniq :: Ord a ⇒ [a] → [a]
  mkUniq = Set.toList ∘ Set.fromList

```

1.4.13 Cardano.BM.Data.Counter

Counter

```

data Counter = Counter
    { cType :: CounterType
    , cName :: Text
    , cValue :: Measurable
    }
    deriving (Eq, Show, Generic, ToJSON)

data CounterType = MonotonicClockTime
    | MemoryCounter
    | StatInfo
    | IOCounter
    | CpuCounter
    | RTSStats
    deriving (Eq, Show, Generic, ToJSON)

instance ToJSON Microsecond where
    toJSON = toJSON ◦ toMicroseconds
    toEncoding = toEncoding ◦ toMicroseconds

```

Names of counters

```

nameCounter :: Counter → Text
nameCounter (Counter MonotonicClockTime _ _) = "Time-interval"
nameCounter (Counter MemoryCounter _ _) = "Mem"
nameCounter (Counter StatInfo _ _) = "Stat"
nameCounter (Counter IOCounter _ _) = "IO"
nameCounter (Counter CpuCounter _ _) = "Cpu"
nameCounter (Counter RTSStats _ _) = "RTS"

```

CounterState

```

data CounterState = CounterState {
    csIdentifier :: Unique
    , csCounters :: [Counter]
    }
    deriving (Generic, ToJSON)

instance ToJSON Unique where
    toJSON = toJSON ◦ hashUnique
    toEncoding = toEncoding ◦ hashUnique

instance Show CounterState where
    show cs = (show ◦ hashUnique) (csIdentifier cs)
    <> " => " <> (show $ csCounters cs)

```

Difference between counters

```

diffCounters :: [Counter] → [Counter] → [Counter]
diffCounters openings closings =
  getCountersDiff openings closings
where
  getCountersDiff :: [Counter]
    → [Counter]
    → [Counter]
  getCountersDiff as bs =
    let

      asNames = map getName as
      aPairs = zip asNames as
      bsNames = map getName bs
      bs' = zip bsNames bs
      bPairs = HM.fromList bs'
    in
      catMaybes $ (flip map) aPairs $ λ(name, Counter _ _ startValue) →
        case HM.lookup name bPairs of
          Nothing → Nothing
          Just counter → let endValue = cValue counter
                        in Just counter {cValue = endValue - startValue}

```

1.4.14 Cardano.BM.Data.LogItem**LoggerName**

A **LoggerName** has currently type *Text*.

```
type LoggerName = Text
```

NamedLogItem

```
type NamedLogItem = LogNamed LogObject
```

LogNamed

A **LogNamed** contains of a context name and some log item.

```

data LogNamed item = LogNamed
  { lnName :: LoggerName
  , lnItem :: item
  } deriving (Show)

deriving instance Generic item ⇒ Generic (LogNamed item)
deriving instance (ToJSON item, Generic item) ⇒ ToJSON (LogNamed item)

```

Logging of outcomes with **LogObject**

```
data LogObject = LogObject LOMeta LOContent
  deriving (Generic, Show, ToJSON)
```

Meta data for a **LogObject**:

```
data LOMeta = LOMeta {
  _tstamp :: {-# UNPACK #-} !UTCTime
  , _tid :: {-# UNPACK #-} !ThreadId
}
deriving (Show)
instance ToJSON LOMeta where
  toJSON (LOMeta _tstamp _tid) =
    object [ "tstamp" .= _tstamp, "tid" .= show _tid ]
mkLOMeta :: IO LOMeta
mkLOMeta =
  LOMeta <$> getCurrentTime
    <*> myThreadId
```

Payload of a **LogObject**:

```
data LOContent = LogMessage LogItem
  | LogValue Text Measurable
  | ObserveOpen CounterState
  | ObserveDiff CounterState
  | ObserveClose CounterState
  | AggregatedMessage [(Text, Aggregated)]
  | KillPill
  deriving (Generic, Show, ToJSON)
```

LogItem

TODO **liPayload** :: ToObject

```
data LogItem = LogItem
  { liSelection :: LogSelection
  , liSeverity :: Severity
  , liPayload :: Text -- TODO should become ToObject
  } deriving (Show, Generic, ToJSON)
```

```
data LogSelection =
  Public -- only to public logs.
  | PublicUnsafe -- only to public logs, not console.
  | Private -- only to private logs.
  | Both -- to public and private logs.
  deriving (Show, Generic, ToJSON, FromJSON)
```

1.4.15 Cardano.BM.Data.Observable**ObservableInstance**

```

data ObservableInstance = MonotonicClock
  | MemoryStats
  | ProcessStats
  | IOStats
  | GhcRtsStats
  deriving (Generic, Eq, Ord, Show, FromJSON, ToJSON, Read)

```

1.4.16 Cardano.BM.Data.Output**OutputKind**

```

data OutputKind = TVarList (STM.TVar [LogObject])
  | TVarListNamed (STM.TVar [LogNamed LogObject])
  deriving (Eq)

```

ScribeKind

This identifies katip's scribes by type.

```

data ScribeKind = FileTextSK
  | FileJsonSK
  | StdoutSK
  | StderrSK
  deriving (Generic, Eq, Ord, Show, FromJSON, ToJSON)

```

ScribeId

A scribe is identified by **ScribeKind** x *Filename*

```

type ScribeId = Text -- (ScribeKind :: Filename)

```

ScribeDefinition

This identifies katip's scribes by type.

```

data ScribeDefinition = ScribeDefinition
  { scKind :: ScribeKind
  , scName :: Text
  , scRotation :: Maybe RotationParameters
  }
  deriving (Generic, Eq, Ord, Show, FromJSON, ToJSON)

```

1.4.17 Cardano.BM.Data.Severity

Severity

The intended meaning of severity codes:

Debug *detailed information about values and decision flow* **Info** general information of events; progressing properly Notice *needs attention; something \rightarrow progressing properly* **Warning** may continue into an error condition if continued Error *unexpected set of event or condition occurred* **Critical** error condition causing degrade of operation Alert *a subsystem is no longer operating correctly, likely requires manual* at this point, the system can never progress without additional intervention

We were informed by the Syslog taxonomy: https://en.wikipedia.org/wiki/Syslog#Severity_level

```
data Severity = Debug
  | Info
  | Notice
  | Warning
  | Error
  | Critical
  | Alert
  | Emergency
  deriving (Show, Eq, Ord, Generic, ToJSON, Read)

instance FromJSON Severity where
  parseJSON = withText "severity" $ \case
    "Debug"    → pure Debug
    "Info"     → pure Info
    "Notice"   → pure Notice
    "Warning"  → pure Warning
    "Error"    → pure Error
    "Critical" → pure Critical
    "Alert"    → pure Alert
    "Emergency" → pure Emergency
    _          → pure Info-- catch all
```

1.4.18 Cardano.BM.Data.SubTrace

SubTrace

```
data NameSelector = Exact Text | StartsWith Text | EndsWith Text | Contains Text
  deriving (Generic, Show, FromJSON, ToJSON, Read, Eq)

data DropName = Drop NameSelector
  deriving (Generic, Show, FromJSON, ToJSON, Read, Eq)

data UnhideNames = Unhide [NameSelector]
  deriving (Generic, Show, FromJSON, ToJSON, Read, Eq)

data SubTrace = Neutral
  | UntimedTrace
  | NoTrace
  | TeeTrace LoggerName
  | FilterTrace [(DropName, UnhideNames)]
```

```

| DropOpening
| ObservableTrace [ ObservableInstance ]
  deriving (Generic, Show, FromJSON, ToJSON, Read, Eq)

```

1.4.19 Cardano.BM.Data.Trace

Trace

A **Trace** consists of a **TraceContext** and a **TraceNamed** in *m*.

```
type Trace m = (TraceContext, TraceNamed m)
```

TraceNamed

A **TraceNamed** is a specialized **Contravariant** of type **NamedLogItem**, a **LogNamed** with payload **LogObject**.

```
type TraceNamed m = BaseTrace m (NamedLogItem)
```

TraceContext

We keep the context's name and a reference to the **Configuration** in the **TraceContext**.

```

data TraceContext = TraceContext
  { loggerName :: LoggerName
  , configuration :: Configuration
  , tracetype   :: SubTrace
  , minSeverity :: Severity
  , shutdown    :: IO ()
  }

```

1.4.20 Cardano.BM.Configuration

see **Cardano.BM.Configuration.Model** for the implementation.

```

getOptionOrDefault :: CM.Configuration → Text → Text → IO (Text)
getOptionOrDefault cg name def = do
  opt ← CM.getOption cg name
  case opt of
    Nothing → return def
    Just o  → return o

```

Figure 1.4: Configuration model

1.4.21 Cardano.BM.Configuration.Model

Configuration.Model

```

type ConfigurationMVar = MVar ConfigurationInternal
newtype Configuration = Configuration
    {getCG :: ConfigurationMVar}
-- Our internal state; see -"Configuration model"-
data ConfigurationInternal = ConfigurationInternal
    {cgMinSeverity      :: Severity
    -- minimum severity level of every object that will be output
    ,cgMapSeverity      :: HM.HashMap LoggerName Severity
    -- severity filter per loggename
    ,cgMapSubtrace      :: HM.HashMap LoggerName SubTrace

Update aggregation

We distinguish an uninitialized from an already initialized aggregation. The latter is properly initialized.

We use Welford's online algorithm to update the estimation of mean and variance of the sample statistics. (see https://en.wikipedia.org/wiki/Algorithms_for_calculating_variance#Welford's_Online)

```

updateAggregation :: Measurable → Aggregated → LOMeta → Maybe Word64 → Aggregated
updateAggregation v (AggregatedStats s) lme resetAfter =
    let count = fcount (fbasic s)
        reset = maybe False (count ≥) resetAfter
    in
    if reset
    then
        singletonStats v
    else
        AggregatedStats $! Stats {flast = v
                                ,fold = mkTimestamp
                                ,fbasic = updateBaseStats (count ≥ 1) v (fbasic s)
                                ,fdelta = updateBaseStats (count ≥ 2) (v - flast s) (fdelta s)
                                ,ftimed = updateBaseStats (count ≥ 2) (mkTimestamp - fold s) (ftimed s)
                                }
    where
        mkTimestamp = utc2ns (tstamp lme)
        utc2ns (UTCTime days secs) =
            let yearsecs :: Rational
                yearsecs = 365 * 24 * 3600
                rdays, rsecs :: Rational
                rdays = toRational $ toModifiedJulianDay days
                rsecs = toRational secs
                s2ns = 1000000000
            in
            Nanoseconds $ round $ (fromRational $ s2ns * rsecs + rdays * yearsecs :: Double)
updateAggregation v (AggregatedEWMA e) _ _ = AggregatedEWMA $! ewma e v
updateBaseStats :: Bool → Measurable → BaseStats → BaseStats

```

```

updateBaseStats False _ s = s {fcount = fcount s + 1}
updateBaseStats True v s =
  let newcount = fcount s + 1
      newvalue = getDouble v
      delta = newvalue - fsum_A s
      dincr = (delta / fromIntegral newcount)
      delta2 = newvalue - fsum_A s - dincr
  in
  BaseStats {fmin = min (fmin s) v
            ,fmax      = max v (fmax s)
            ,fcount = newcount
            ,fsum_A = fsum_A s + dincr
            ,fsum_B = fsum_B s + (delta * delta2)
            }

```

Calculation of EWMA

Following https://en.wikipedia.org/wiki/Moving_average#Exponential_moving_average we calculate the exponential moving average for a series of values Y_t according to:

$$S_t = \begin{cases} Y_1, & t = 1 \\ \alpha \cdot Y_t + (1 - \alpha) \cdot S_{t-1}, & t > 1 \end{cases}$$

The pattern matching below ensures that the **EWMA** will start with the first value passed in, and will not change type, once determined.

```

ewma :: EWMA → Measurable → EWMA
ewma (EmptyEWMA a) v = EWMA a v
ewma (EWMA a s@(Microseconds _)) y@(Microseconds _) =
  EWMA a $ Microseconds $ round $ a * (getDouble y) + (1 - a) * (getDouble s)
ewma (EWMA a s@(Seconds _)) y@(Seconds _) =
  EWMA a $ Seconds $ round $ a * (getDouble y) + (1 - a) * (getDouble s)
ewma (EWMA a s@(Bytes _)) y@(Bytes _) =
  EWMA a $ Bytes $ round $ a * (getDouble y) + (1 - a) * (getDouble s)
ewma (EWMA a (PureI s)) (PureI y) =
  EWMA a $ PureI $ round $ a * (fromInteger y) + (1 - a) * (fromInteger s)
ewma (EWMA a (PureD s)) (PureD y) =
  EWMA a $ PureD $ a * y + (1 - a) * s
ewma _ _ = error "Cannot average on values of different type"

```
